

## SPECIALIST APPENDICES

### Appendix 1: Scientific dating results

The results of the radiocarbon dating programme are given in Tables A1.1-A1.4 and Table A1.5 presents the results obtained by Optically Stimulated Luminescence dating of sediments (OSL) (see Chapter 2).

#### Radiocarbon dating by Rebecca Nicholson

Thirty samples of bulk organic sediment, wood and charcoal were processed by Beta Analytic Inc., Florida, USA (lab. code Beta) for conventional radiometric dating or (in the case of Beta-152742 only, see Table A1.3) AMS dating. Subsequently, during the post-excavation analytical phase 34 samples of wood, sediment, charred grain, cremated bone and charred pot residues were submitted to the Scottish Universities Environmental Research Centre (lab. code SUERC (GU)) in East Kilbride, Scotland for Accelerator Mass Spectrometry (AMS) dating. Unfortunately two dates on charred residues adhering to potsherds failed, including potsherd SF12 from FRU01 (GU-18957; context 17) and a potsherd from TGW00 TR23 (GU-18955; context 38).

Where sediment (peat) samples were processed by Beta Analytic they were combusted and dated by Liquid Scintillation Spectrometry (LSC). In some cases, wood was extracted from the peat and this was dated rather than the submitted sediment. For sediment samples processed for AMS dating by SUERC, the laboratory standard methodology was used and the humic (alkali soluble) fraction was extracted and dated. The radiocarbon results are quoted in accordance with the international standard known as the Trondheim convention (Stuiver and Kra 1986). They are conventional radiocarbon ages, where 0 BP is the year 1950 (Stuiver and Polach 1977; Mook 1986). All dates have been calibrated using datasets published by

Reimer *et al.* (2004) and the computer program OxCal (v3.10) (Bronk Ramsey 1995; 1998; 2001) with the end points rounded out to 5 or 10 years. The calibrated date ranges cited in the tables, as in the text, are those for 95.4% ( $2\sigma$ ) confidence.

#### OSL dating by Edward Rhodes and Rebecca Nicholson

A suite of 7 sediment samples, from two sections from Prince Regent Lane and Movers Lane, were collected. Samples CT1 and CT3 (see Table A1.5) were collected from a section exposed in the east edge of TP66 at the junction of the A13 with Prince Regent Road. Sample CT1 was from context 204, a sandy horizon 2.08m below the ground surface. Sample CT3 came from context 212, a sandy silt 2.75m below the ground surface. Samples CT4 and CT6 were collected from the south edge of TR6 at Movers Lane. Sample CT4 came from context 514, within sandy horizon 0.8m below the ground surface. Sample CT6 came from context 515, a sandy silt with pebbles, at 1.20m below the ground surface.

Optically Stimulated Luminescence (OSL) dates based on sand-sized quartz grains from these four samples were measured. Equivalent dose ( $D_e$ ) determinations were made using a single aliquot regenerative dose (SAR) technique. Uranium (U), thorium (Th) and potassium (K) concentrations were determined *in situ* using sodium iodide gamma spectrometry. The cosmic dose rate contribution was estimated as a function of geomagnetic latitude, altitude and overburden using the formulae of Prescott and Hutton (1994). The *in situ* water content of each sample was measured and used to calculate dose rate attenuation. Full methodological details and a discussion of the results are available in the site archive.
