## Abstract

This report is intended to identify the archaeological implications of any development work to be carried out at St Luke's Church Old Street. The church was designed by Nicholas Hawksmoor and John James and opened in 1733. (p20)

The crypt of the church is known to contain burials from 1740-1853, both within vaults and buried below the floor. The likely preservation of this material should allow identification of the burials within from the attached coffin plates. (p24-26)

If the crypt is sufficiently undisturbed to obtain a reasonable named sample then the burials within are likely to be considered of national importance. (p42)

The parish records and burial registers for the church are fairly comprehensive. The burial registers exist for the whole period of the use of the crypt. (p47)

As access to the crypt was not possible it has been difficult to gather a full picture of the present state of the structure and its contents. Some disturbance has occurred but the extent cannot be determined at present. (p26)

Current information suggests that there are problems of structural integrity with both the church and the crypt and that, at present, it would not be safe to work within the crypt. Both require remedial works before any work could commence. (p40)

Until the engineering problems have been solved, it is very difficult to determine the extent of the required archaeological work. Consultation with the design and engineering teams would be required to produce a detailed methodology. (p43)

The church is an historic building and the crypt below is an integral part of it which should be recorded archaeologically. (p43)

There is a low potential for any earlier archaeological remains surviving on the site due to the disturbance caused by the present structure and its associated graveyards. Burials from the churchyard are likely to be considered as regionally important, as part of the ongoing study of London's population from its skeletal remains. (p13-20)

## Site Location

CL200

The site is located in the parish of St Giles without Cripplegate, in the southern part of the London Borough of Islington.

The site is bounded by Helmet Row to the west, Ironmonger Row to the east, Old Street to the south and Mitchell Street to the north.

The Ordnance Survey National Grid Reference for the site centre is TQ 32320 82423.

Museum Of London site code: SLU96

## Origin & Scope of the Report

This report has been commissioned from the Museum of London Archaeology Service (MoLAS) by Gill Andrews, Consultant Archaeologist, on behalf of her client Levitt Bernstein Associates, acting for the London Symphony Orchestra.

The report has the status of an Archaeological Desk Top Assessment and has been prepared within the terms of the relevant Standard specified by the Institute of Field Archaeologists, which states that:

*A Desk-based Assessment will determine, as far as is reasonably possible from existing records, the nature of the archaeological resource within a specified area using appropriate methods of study which satisfy the stated aims of the project, and which comply with the Codes of Practice of the Institute of Field Archaeologists.*

A Desk-Based Assessment is more closely defined as:

*An assessment of the known or potential archaeological resource within a specified area or site on land or underwater, consisting of a collation of existing written and graphic information in order to identify the likely character, extent, quality and worth of the known or potential archaeological resource in a local, regional, or national context as appropriate.*

The same document goes on to point out that desk-based assessments are undertaken in order that the known or potential archaeological resource can be assessed and appropriate responses made. These responses may consist of one or more of the following:

*the formulation of a strategy to ensure the recording, preservation or management of the resource.*

ALROO

*the formulation of a strategy for further investigation, whether or not intrusive, where the character and value of the resource is not sufficiently defined to permit a mitigation strategy or other response to be devised.*

*the formulation of a proposal for further archaeological investigation within a programme of research.*

The Standard stresses that on those occasions when a Desk-based Assessment is commissioned in advance of submission of a planning application:

*it is appropriate for any proposals for Desk-based Assessment to be agreed with the planning archaeologist in advance, so that the aims and methodology are agreed and excessive cost not incurred. In such circumstances, matters of confidentiality will need to be carefully considered by all parties involved.*

### Current Practice

Current practice has been further defined by the Association of County Archaeological Officers. In this definition, the product of a Desk-based Assessment should be a report that:

*assembles, summarises and orders the available evidence.*

*synthesises it and places it in the local and/or regional context.*

*comments on its quality and reliability and indicates how it might be supplemented by Field Evaluation so as to provide the information required for planning purposes.*

In addition, current archaeological practice is increasingly determined by a number of recent documents issued by English Heritage in response to the advice set out by the Department of the Environment. The most comprehensive of these documents is the "Management of Archaeological Projects" (known as MAP 2). This document recognises that large archaeological projects may be preceded by one or more preliminary phases of evaluation which:

*... will almost invariably commence with a desk top study. In those cases where such study yields insufficient information, rapid and limited fieldwork may follow. The purpose of such fieldwork is to define, as far as possible, the likely nature and extent of the archaeological deposits under consideration.*

Figure 3 Agas Map of 1560

They also provide information useful for identifying potential options for minimising or avoiding damage. On this basis, an informed and reasonable planning decision can be taken...

### **The Unitary Development Plan**

The Unitary Development Plan for the London Borough of Islington states in Policy D42 that:

*The Council will promote the conservation, protection and enhancement of the archaeological heritage of the Borough and its interpretation and presentation to the public.*

*In particular it will:*

- i) seek to ensure that the most important archaeological remains and their settings are permanently preserved;*
- ii) on other sites of archaeological significance, ensure that provision is made for archaeological investigation and excavation and the recording and publication of results;*
- iii) encourage co-operation between landowners, developers and archaeological organisations in accordance with the British Archaeological and Developers Liaison Group Code of Practice.*

It continues in Policy D43:

*Within archaeological priority areas.....all planning applications involving groundworks must be accompanied by an archaeological evaluation, commissioned by the applicants from the Museum of London or other suitable body acceptable to the Council. In accordance with ... PPG16 evaluations may also be required in other cases, where the Council has evidence that archaeological remains may be present.*

It also states in Policy D44 that:

*In appropriate cases the Council will request the developer to enter into a Section 106 agreement to ensure that an archaeological investigation and excavation is carried out by the Museum of London or other suitable body, to the satisfaction of the Council. Such agreements should cover arrangements for access, funding and facilities. The Council may also impose planning conditions to achieve satisfactory heritage safeguards.*

The site borders an archaeological priority area as identified within the London Borough of Islington's Unitary Development Plan.

*If physical preservation in situ is not feasible, an archaeological excavation for the purposes of 'preservation by record' may be an acceptable alternative. From an archaeological point of view, this should be regarded as a second best option.*

*Agreements should also provide for the subsequent publication of the results of any excavation programme.*

*Development plans should reconcile the need for development with the interests of conservation - including archaeology. Detailed development plans should include policies for the protection, enhancement and preservation of sites of archaeological interest, and their settings.*

*Decisions by planning authorities on whether to preserve archaeological remains in situ, in the face of proposed development, have to be taken on merit, taking account of development plan policies and all other material considerations - including the importance of the remains - and weighing these against the need for development.*

*Planning authorities, when they propose to allow development which is damaging to archaeological remains, must ensure that the developer has satisfactorily provided for excavation and recording, either through voluntary agreement with the archaeologists or, in the absence of agreement, by imposing an appropriate condition on the planning permission.*

Where archaeological features are likely to be encountered, strategies should be developed to deal with them. These may include preservation *in situ*, by limiting the archaeological impact, redesigning the building plan or raising the floor levels, or preservation by record.

If the last is the favoured or apposite course for sub-surface deposits, archaeological trial excavations to assess the nature, depth, level of survival etc. may be conducted. Where preliminary research suggests survival of important archaeological remains, PPG 16 states that:

*It is reasonable for the planning authority to request the prospective developer to arrange for an archaeological field evaluation to be carried out before any decision on the planning application is taken. This sort of evaluation is quite distinct from full archaeological excavation. It is normally a rapid and inexpensive operation, involving ground survey and small scale trial trenching, but it should be carried out by a professionally qualified archaeological organisation or archaeologist. Evaluations of this kind help to define the character and extent of the archaeological remains that exist in the area of a proposed development, and thus indicate the weight which ought to be attached to their preservation.*

## Objectives of the Report

The primary object of this report is to attempt to identify and assess any archaeological deposits or remains that might be threatened by demolition, ground preparation or construction works associated with the redevelopment of the site.

The study is intended to form the first stage in the process of archaeological investigation. If warranted by the archaeological potential, further assessments, exploratory trial work, watching brief observations or full scale excavation within the redevelopment area may be required before that process is complete. It is, therefore, a further object of this report to consider all relevant information with a view to informing any future discussion of the most appropriate strategy for dealing with any surviving archaeology on the site.

## Methodology

The work has been carried out in accordance with the model brief issued by the English Heritage (London Division) Planning Advisory Service. It follows guidance given by the Institute of Field Archaeologists (1993) and by the Association of County Archaeological Officers (ACAO 1993).

In summary, the work has involved:

- identifying the sources available for consultation;
- assembling/consulting and examining these sources;
- consulting specialists within MoLAS as appropriate.

The degree to which archaeological deposits actually survive on the site will depend on previous land use. Thus an assessment is made of the destructive effect of the previous and present activity and/or buildings, from the study of available plan information, ground investigation reports, etc.

The data from archaeological excavations and other works in the vicinity of the site have been supplemented by a consideration of both the Geological and Historical backgrounds of this part of the London Borough of Islington, insofar as these are currently understood. This has required the consultation of a range of cartographic, documentary and academic sources, which are detailed in the accompanying Bibliography.

## THE LEGISLATIVE FRAMEWORK

### Planning Policy Guidance

The Department of the Environment issued its Planning Policy Guidance Note 16 (PPG16), in November 1990. This is intended as guidance for planning authorities, property owners, developers, archaeologists, amenity societies and the general public. The document sets out the policy of the Secretary of State on archaeological remains on land and how they should be preserved or recorded. It applies to both urban and countryside environments and gives advice on the handling of archaeological remains and discoveries under the development plan and control systems.

The numerous recommendations of this important document are rapidly being integrated into local development plans and have been endorsed by a number of organisations concerned with the national heritage. A recent English Heritage publication discusses the strategies which can be applied to the Archaeology of England, incorporating the key points of the document. These can be summarised as follows:

*Archaeological remains should be seen as a finite, and non-renewable resource, and in many cases highly fragile and vulnerable to damage and destruction. Appropriate management is therefore essential to ensure that they survive in good condition. In particular, care must be taken to ensure that archaeological remains are not needlessly or thoughtlessly destroyed. They can contain irreplaceable information about our past and the potential for an increase in future knowledge. They are part of our sense of national identity and are valuable both for their own sake and for their role in education, leisure and tourism.*

*Where nationally important archaeological remains, whether scheduled or not, and their settings, are affected by a proposed development there should be a presumption in favour of their physical preservation.*

*The key to informed and reasonable planning decisions is for consideration to be given early, before formal planning applications are made, to the question of whether archaeological remains are known to exist on a site where development is planned and the implications for the development proposal.*

*When important remains are known to exist, or when archaeologists have good reason to believe that important remains exist, developers will be able to help by preparing sympathetic designs using, for example, foundations which avoid disturbing the remains altogether or minimise damage by raising ground levels under a proposed new structure, or by careful siting of landscaped or open areas. There are techniques available for sealing archaeological remains underneath buildings or landscaping, thus securing their preservation for the future even though they remain inaccessible for the time being.*

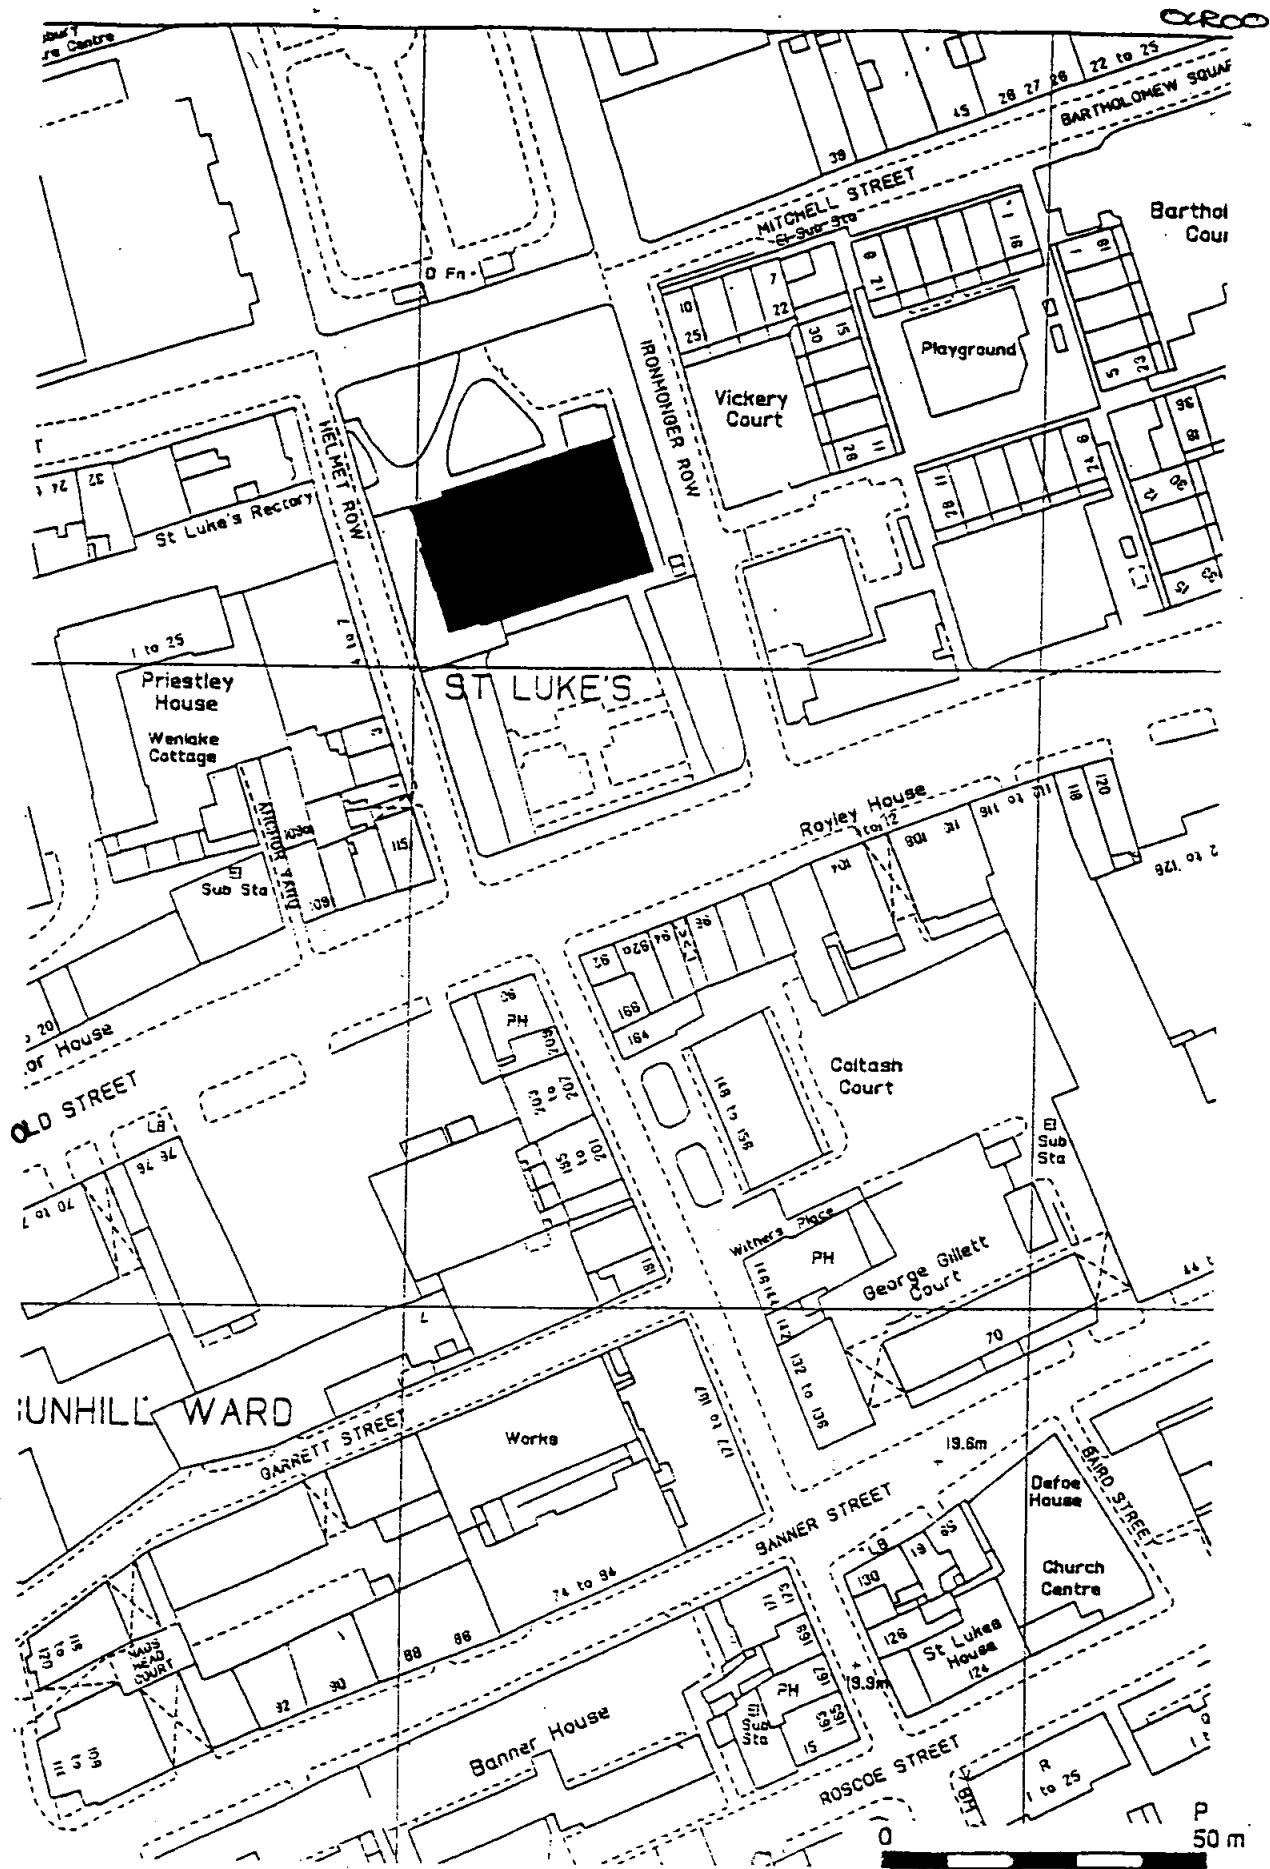

Figure 2 Site Location, scale 1:1250

## Geological and Topographic Background

The site lies on the Third Terrace above the river Thames. Where not quarried away the underlying natural substrate is brickearth, overlying Thames terrace gravels. These would have provided a moderately free draining medium with drainage following the ground slope. To the east lay the valley of the Walbrook stream which arose in Hackney, flowed through Hoxton/Shoreditch and bisected the City of London. This watercourse had a major effect on the topography and development of the City.

The site is basically flat, present day ground level is at around 20.5m OD.

## Historical Background

Within the natural deposits of the area are found Palaeolithic and Mesolithic remains (450,000 - 4,000 BC). The London region is an important area for finds of Palaeolithic implements which elsewhere in Northern Europe have been removed by the action of successive Ice Ages. The distribution of such finds is more or less random and the chances of their occurrence on individual sites are very low; however two Lower (earlier) Palaeolithic flint hand axes have been recovered from within 400m of the site.

Remains are rarely encountered in central London for the settled periods of prehistory (4,000 BC - AD 50); however a socketed wrought iron spearhead, considered to be Iron Age (700 BC - AD 50), was found at Golden Lane (c. 200m from the site).

The Roman city of Londinium was founded soon after the conquest of lowland Britain, ca. AD 50 and the area of the site is thereafter part of the hinterland of the largest and most complex urban settlement in Britain.

A large fort occupied the area of the city closest to the site in Roman times. It has been assumed to have been founded as a response to the sacking of the city in the native revolt of AD 60 and the recent identification of a tile of the British fleet (Classis Britannia, inscribed CLBR), from excavations at 34 Noble Street, may indicate a continued military presence to the 3rd century but is by no means conclusive.

It has been suggested by Grimes that present day Old Street is a Roman road, part of an east-west communications line of which the existing road is only a small part. On the early maps 'Old Street' does not appear as a continuous feature, but in spite of breaks in the Bethnal Green area it appears that to the east it made for the crossing of the River Lea at Old Ford. To the west the course of the road has various possible courses. Its present course in Clerkenwell and Farringdon is apparently a fairly recent development. One 17th century version by way of Long Acre, Kingsgate (the equivalent of the northern part of modern Kingsway), and Theobalds Road was used by King James I to by-pass the City on his way to his country seat at Theobalds, near Cheshunt. Another version of it appears to have joined Watling Street (modern day Oxford Street) to the north-west of St Giles-in-the-Fields.

Figure 4 Faithorne and Newcourt's map of 1658

The link with the Roman road has led to the identification of 'Old Street' itself as a Roman road, though the fact that it ignores the City and may therefore have been in existence before the Roman occupation has also been noted by Margary. Old Street is often regarded as a branch of Oxford Street, on the assumption that together they may have formed a prehistoric route which was taken over by the Romans and developed a more southerly branch along the line of Holborn with the foundation of London.

Grimes suggested that Old Street may have had a more important purpose than an alternative to a main route, and that it may have formed part of a link, located on the 50 foot gravel terrace, between two important river crossings, at Old Ford and Putney, and therefore becomes part of a land route between the area to the north-east and east of London and that to south-west and south.

Rodwell, while trying to define the limits of London's town zone, suggested that the northern boundary was the early road from Colchester to Silchester, believed to underlie Old Street.

Gravelled surfaces with stratified Roman coins were revealed in Victorian sewer excavations in Old Street during 1867. A vase and bronze armlets were found c. 290m & 340m east of the site in 1912 and they may have been roadside grave goods. A coin of Nero was recovered in 1941. From Whitecross street, at c 250m to the south, a coin and gaming piece were found and a residual sherd of Samian pottery was found in a secondary (not Roman) deposit on the Whitbread brewery site (WTC76). These finds are scattered and would not have led to the build up of a stratified sequence of deposits as occurs often within the city walls.

There are no historical records or archaeological finds which throw light on the study area for the early medieval period. Finsbury was a manor in later medieval times and has been given a Saxon origin by some scholars (the *burh*, or fortified residence, of the family *Finnes*); however it is likely that it was a later medieval creation by subdivision. There is certainly no extant early charter, and its name maybe derived from fen, describing the local topography of the Moorfields to the south east. To the south west of the site lay a signal tower called the Barbican, and later a house built on the spot is called Base Court. It is likely that this is a Saxon foundation as it is cognate with Bassishaw (*Basingahaga*) a parish, ward and probable Saxon estate in the same fashion as the parish of St Mary Staining has its origin in the estate of the manor of Staines (*Stainingahaga*).

When the Domesday book was compiled the nearest Manor mentioned is that of Hoxton and at that time this manor, together with Islington, the liberty of Bishopsgate and the Manor of Stepney belonged to the Canons of St Paul's Cathedral. The later manor of Finsbury was also part of their estate. The large area they controlled (most of the modern boroughs of Tower Hamlets, Hackney and large parts of Islington) reflecting the political necessity for areas near the city to be in the hands of Norman placemen: the Bishop and other Diocesan appointments.

Figure 5 Morgan's map of 1682

The area around the city was largely taken up with varieties of market gardening or dairy pasture. A later medieval tenement in Golden Lane had the name of *Le Mykelvine* (*trans lit* the Much Vine). The area of the ridge, to the east of the site, became built up as a suburb of the city. Whitecross Street is first recorded as *Everardes Wellestrata* in 1253, although then it may only have ran as far north as Chiswell Street. It is recorded as *Wytecroychstrate* in 1285. The Abbot of Ramsey maintained an Inn, or large townhouse, on the corner of Whitecross Street and Beech Street. To the east of the site lay the three open fields of Finsbury manor (Mallow, Finsbury & Bunhill).

By the 15th century the land was owned by the Knights of St John. This can be seen from a transcript of St John Cartulary, the original document held at the Museum of the Order of St John of Jerusalem, Clerkenwell - Baidon Translation of Cotton MS Nero VI

*The Prior's charter of a vacant parcel of land in Old Street*

*Indenture by which Brother Walter Grendon, Prior of the Hospital, lets to farm to William Russell, citizen and fishmonger of London, a vacant parcel of land lying in Old Street, Co Middlesex, in breadth between the land of the said William on the west and the land of the prebend os St Paul's, London, called Wallokkesberne on the east, and in length between the land of the said prebend on the north and the highway on the south; from Christmas next for 60 years at a rent of 3s 4d with power of distress, and of re-entry if no sufficient distress can be found. Dated at Clerkenwell (Date not filled in, Grendon was Prior 1400-1416).*

*The Hospital charter of seven gardens and two cottages built in Old Street.*

*Indenture by which Prior Robert Mallory lets to farm to John Grene seven gardens lying together with two cottages built upon them, between the lane leading to Wallokkesberne on the east, the high street called Old Street on the south, the highway leading to Islington on the west, and land of Thomas Frowyke on the north. Also another garden near Old Street on the south, the tenement of Hugh Mayne on the west, and the land of said Thomas Frowyke on the north and east, with the issues and profits of the courtyard to the same gardens and cottages belonging; for 4-score years from the Nativity of St John the Baptist last (1439) at a rent of 33s 4d. The tenants to keep the premises in repair, as to the fences, hedges, ditches etc and to discharge all burdens and services due thereon; with power of distress, and of reentry if rent is in arrears for 3 months or the premises in disrepair. Given at our house of Clerkenwell at the celebration of our Chapter there, Tuesday 30 June 17 Henry VI.*

There is a reference for the site in the Greater London Sites and Monuments Record as being the possible location of a medieval manor house, recorded as St Lukes Manor House. There is no other known reference to this and it must be considered suspect, as most of the land in the area was owned by the Knights of St. John, while the parish name of St. Luke's only appears after the foundation of the church in 1711. The reference may originally have been derived from the 1560's Agas map, which shows buildings on the site.

In Tudor times the area around the site was still largely open and most likely used for horticultural purposes. The Drapers Company built almshouses north of Beech Street and Richard Gallard founded some on Golden Lane, which continued a medieval tradition of almshouses and hospitals on the city fringes that proceeded well into the post-medieval period.

Stow in his Survey of London, first published in 1598, describes Old Street thus;

*'...the way stretcheth vp towards Iseldón and on the right hand, or East side, at a Red Crosse turneth into Ealdstreete, so called, for that it was the old high way from Aldersgate streete for the Northeast parts of England before Bishopsgate was builded, which streete runneth East to a Smithes Forge, sometimes a Crosse before Shoreditch Church, from whence the passengers and Carriages were to turne North to Kings land, Tottenham, Waltham, Ware, &c.'*

The most obvious archaeological deposit associated with the beginning of the post-medieval period is a large landfill dump to the north of the City. Often referred to as the filling of the Moorfields marsh it is clear now that it far exceeded the boundaries of the marsh itself. The deposits were formed mostly of a mixture of nightsoil and demolition debris and at Whitbread's brewery were 3m thick. Under waterlogged conditions sometimes leather waste is also recovered and occasionally important industrial waste is found. At Old Broad Street crucible fragments were recovered from Mansell's monopoly *Cristallo* glassworks: a factory which employed a free, international workforce, drawing on the most advanced glassmaking techniques of the Muranesi glasshouses and decorative skills from the Netherlands.

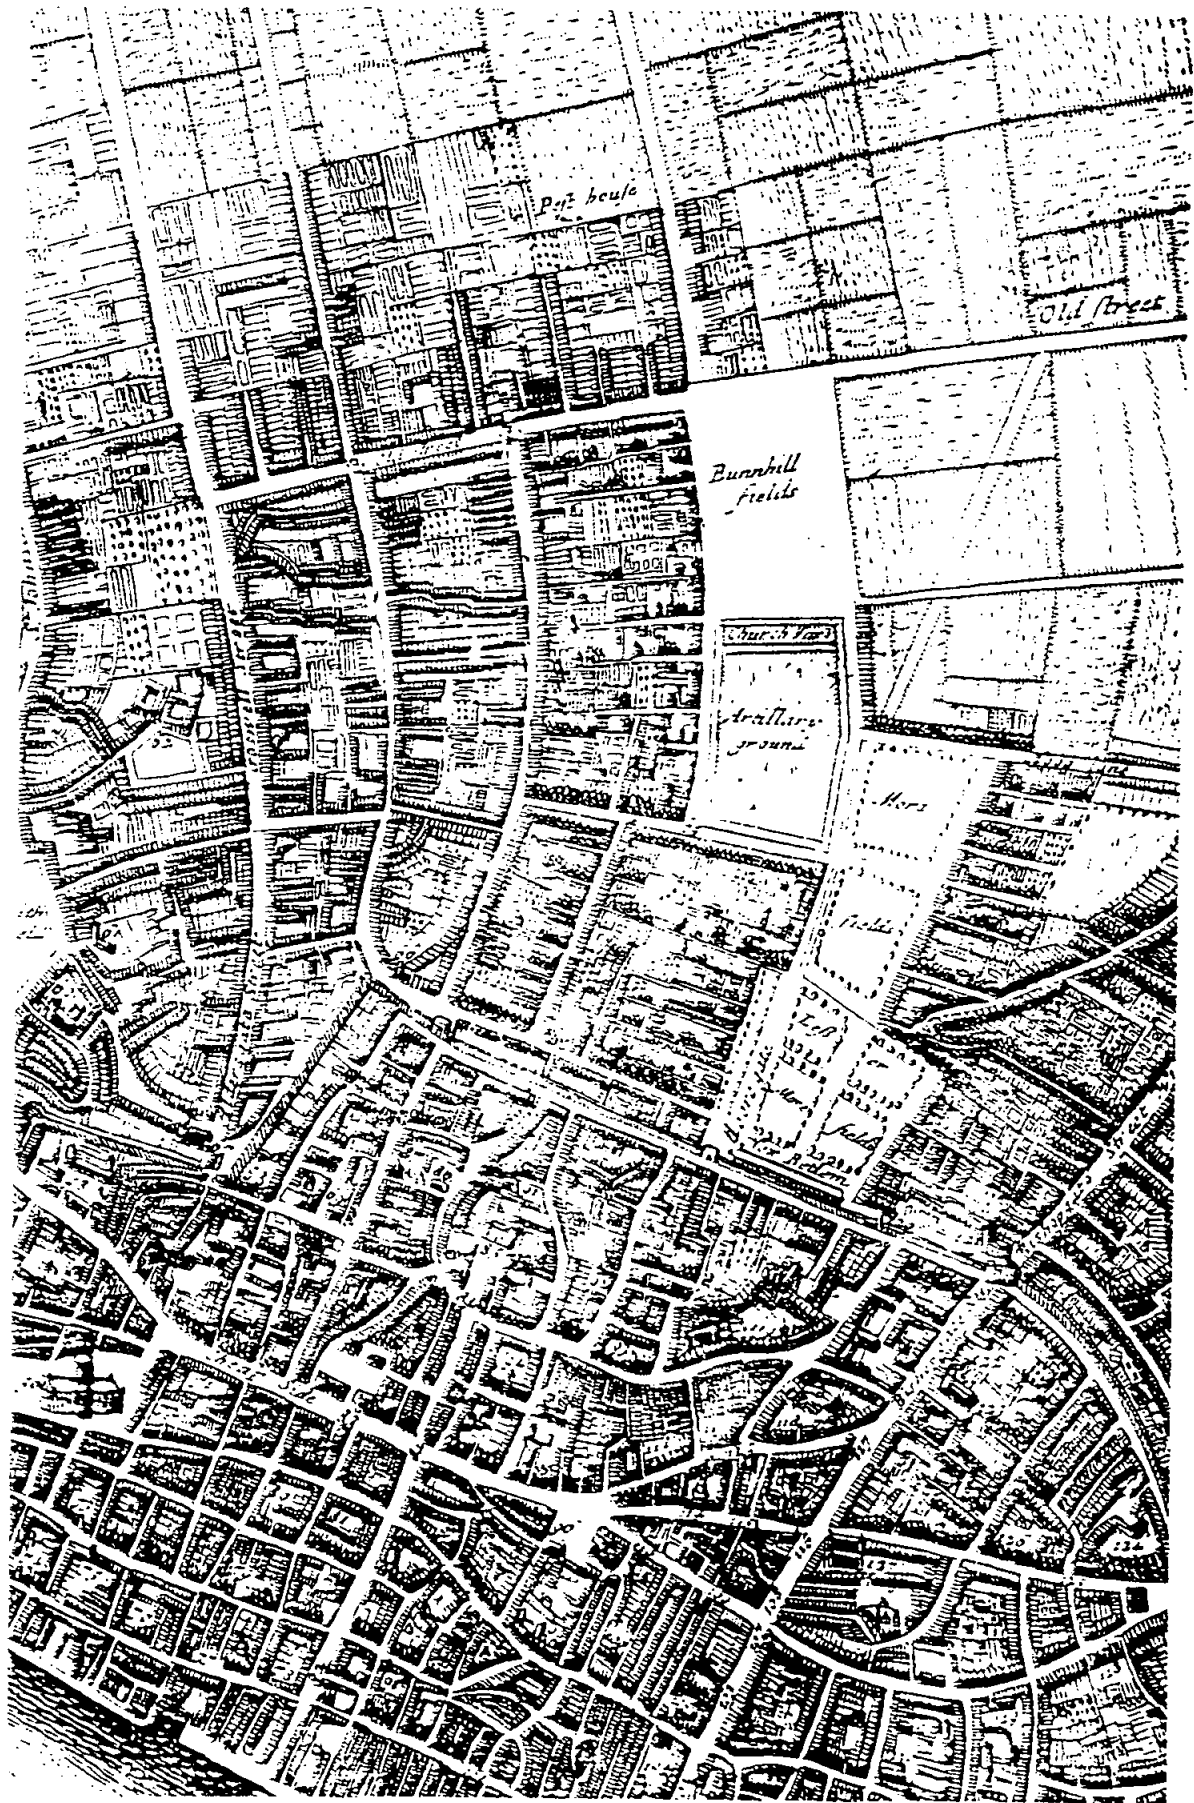

Figure 6 Jacob de la Feuille's Map of 1688-1702

In part this deposit represents a growth in the productive resources of the city as it often fills brickearth quarries used to rebuild London in brick; quarries which are not always recognised in the archaeological record as their sides often exceed the exposures examined by archaeologists. Also, the increased use of coal as a fuel meant that nightsoil was less useful as an agricultural fertiliser. The increase of the City's population at this time, as guild restrictions eased and the closure of the monasteries gave space to expand, may have overburdened traditional means of disposal.

### St Luke's Church

The church is located at the extreme north-west limit of the 'Moorfields Marsh'. In theory it should be on the drier ground, although accounts made at the time of the construction of the church mention marshy conditions.

St Luke's Old Street was constructed as part of the Commissions for Fifty New Churches, which were set up in 1711, to alleviate the lack of places of worship caused by the Great Fire along with rapid population growth at this time. The committee calculated that an additional 72 churches were required, which was rounded down to a convenient figure of 50, of which only 12 were actually built.

St Luke's Old Street, was built to meet the growing requirements of that part of the town, the parish being taken out of St Giles Cripplegate parish. In 1711 St Giles Cripplegate was reported to have 4,600 houses. The area of St Giles Cripplegate which was used to form the parish of St Luke's was known as The Lordship.

The land to build the church was acquired from the Ironmongers' Company for £900, although as can be seen from the minute books of the Commission for Building Fifty New Churches (appendix 1) the progress towards construction was a long process.

The architect of the church is traditionally disputed; the body of the church is possibly by John James, the west tower, spire and flanking staircase wings by Nicholas Hawksmoor. The final cost of the church was £15,579. It has often been wrongly attributed to George Dance the Elder, who was a member of the vestry and who was buried there in 1768, a black marble slab being provided by his children 20 years later, which has now gone.

The church was consecrated on the festival of St Luke, 1733, by Dr Hare, Dean of St Paul's and Bishop of Chichester,

The church seems to have started subsiding soon after completion. The first account of repairs dates from 1734, with further attempts in 1869, 1877, 1914 and 1951. The church suffered some War damage in the 1940's but it is thought that the dry summer of 1956, combined with the effect of heavy bombing on nearby sites, caused more recent movement. In 1959 the roof was removed which, not surprisingly, has had a disastrous effect on the rest of the structure. The church is currently a 'ruin' with the subsidence evident on the north and east walls.

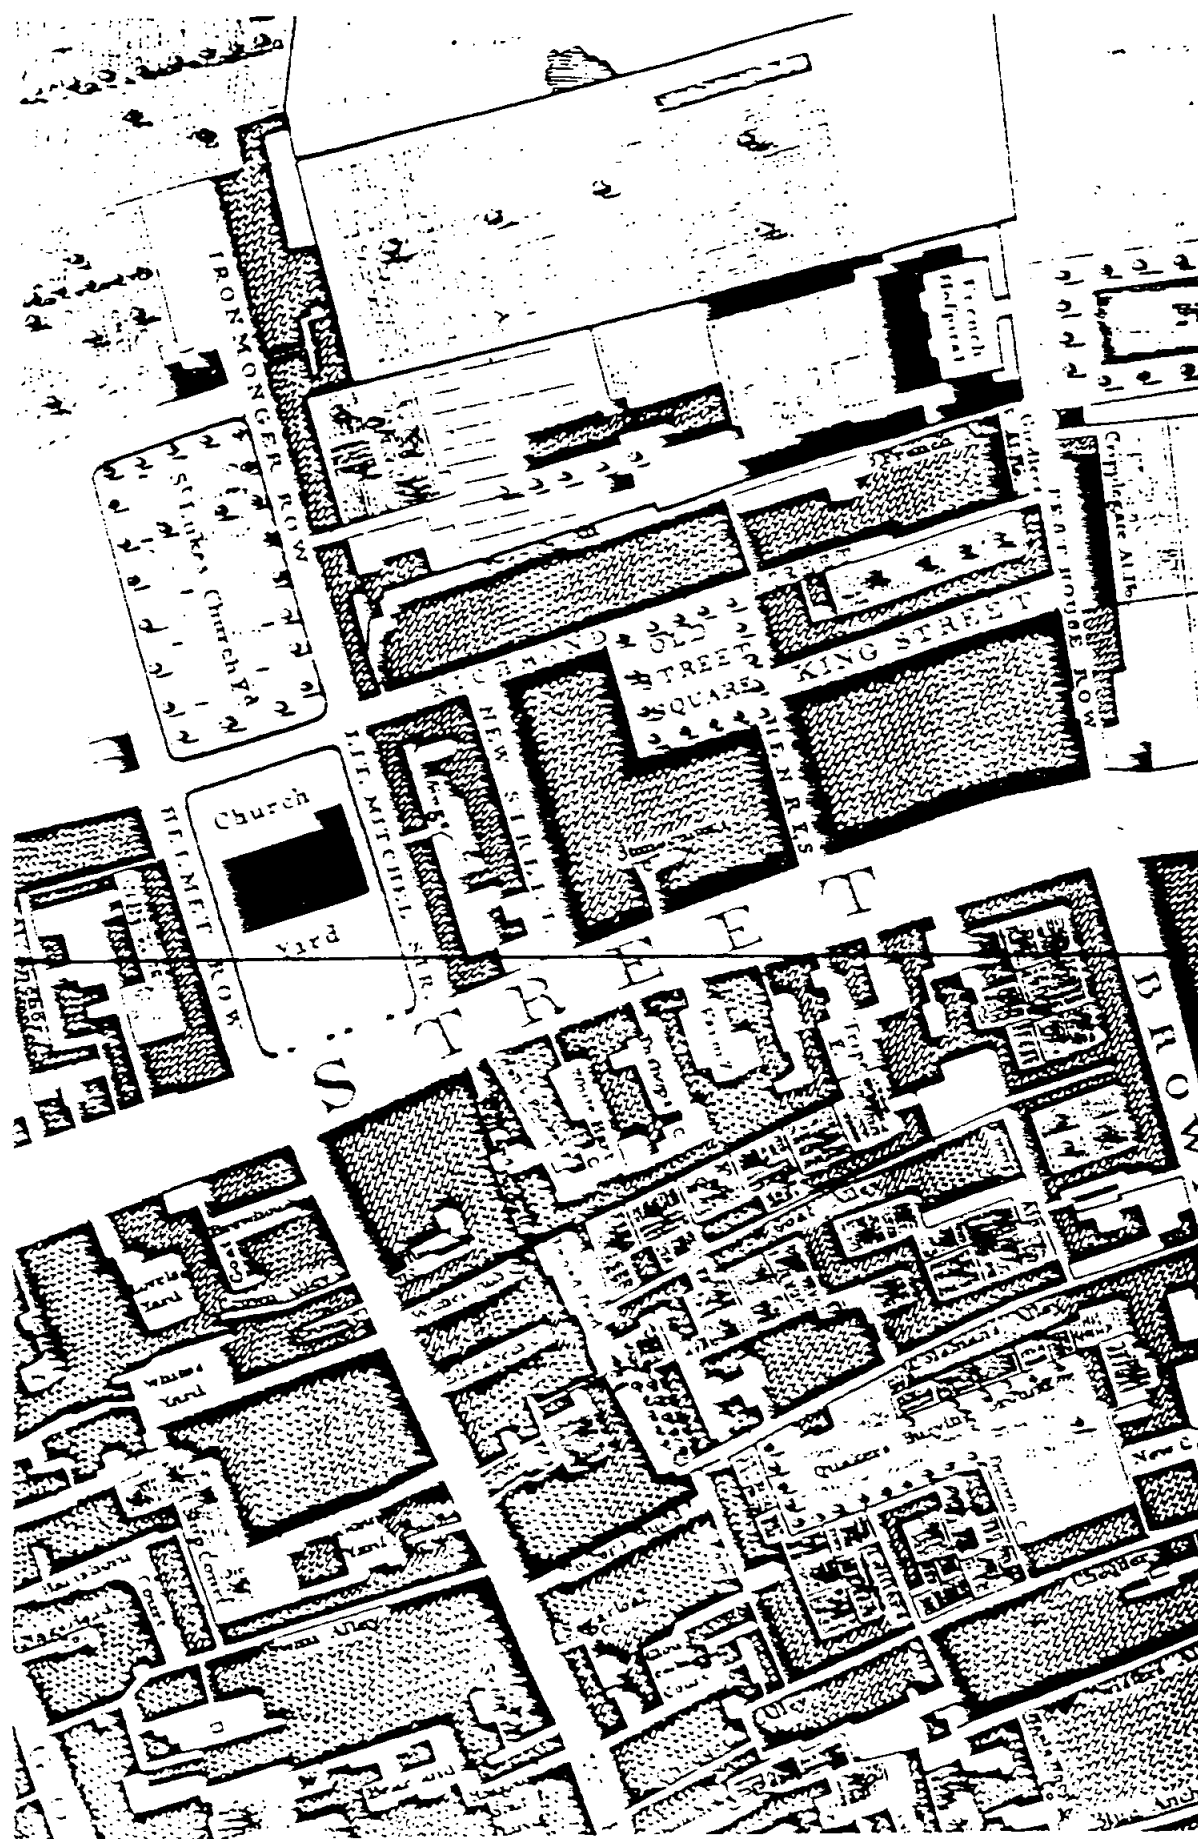

Figure 7 John Rocques Map of 1740

A description of the church prior to its virtual destruction can be obtained from *London Churches Ancient & Modern* by T. Francis Bumpus, published in 1908.

*Externally it is a plain, substantial stone structure, devoid, however of a sanctuary, with a western tower rising properly from the ground, and surmounted by a fluted obelisk of graceful outline. On either side of the tower are square erections roofed with lead domes and containing the staircases to the galleries.*

*Within, St Luke's is dignified and imposing, and divided into a nave and aisles by lofty colonnades of the Ionic Order. The roof over the nave is semi circular, as are those of the aisles which are vaulted transversely, in as many compartments as there are arcades, from the tall Ionic columns to consoles in the walls. The stonework is painted white, and the details of the columns, etc., are picked out in gold with pleasing effect.*

*Rich stained glass—mostly by Messers Heaton and Butler—fills the double series of windows on either side, the same artists being responsible for the very beautiful paintings in the three square panels of the altarpiece which has been profusely covered with gold. The glass in the east window, composed of a round headed centre and square wings, was inserted sixty years ago by Clutterbuck. The subjects; the Nativity, Crucifixion and Ascension, are treated in the Cinquecento Flemish style, and much of the colouring is rich and fine.*

*Unfortunately, by some blunder in taking the dimensions of the window, the central picture was painted much too large for its place, and it had to be cut down through figures in every direction. The group, which has caught all the coarse literal fidelity of the cinquecento School, is confused, there is an almost total absence of symbolical allusion, and of the devotional effect there is not a trace.*

*There are galleries on the north, south and west sides, and in the latter, which is supported on Ionic columns, is the organ, a large, plain instrument, presented to the church by a brewer of Old Street, named Buckley. Built in 1734, this organ in St Luke's is ascribed by some to Bridge, by others to Jordan, and is said to be the first church organ to which the tremulant was applied. The swell, sub, and super octaves were probably the earliest made in England.*

*This organ in St Luke's has some interesting associations. The Churchwardens of St Luke's had a property left them by the Ironmongers Company for church purposes, which grew into so large a sum that they did not know what to do with it. After much discussion it was decided that it should be spent on enlarging and improving the organ, the work to be done by Messers Gray and Davison. Davison was an old friend of the distinguished English church composer, Henry Smart, who at that time (1843 or thereabouts) greatly wished to have the use of a large organ, and thus it was not long after the giving of the order, Henry Smart heard of the fine instrument that was being built in St Luke's, Old Street, and the churchwardens received an application from him for the post of organist.*

00000

*It should be mentioned that the then organist of St Luke's was blind, had given much dissatisfaction, and was deemed unfit to manipulate the new organ properly. Henry Smart was then a well-known man, and when he told the churchwardens that his chief object was to secure the use of a fine organ, and that he would, therefore, come for £50 per annum, they accepted his offer, and also agreed to his one stipulation, that sufficient money should be allowed him to pay a professional quartet in his choir. He held the post of organist from 1844 to 1864.*

The organ case and font are now in St Giles without Cripplegate, with which the parish of St Luke's was reunited in 1959.

A list of 1759 shows the plate weighed in ounces, drachms and grammes; the curtains and curtain rods were counted; and objects in the vestry room were enumerated: 'an umbrella, a table of fees, an Almanack, 8 Pewter Dishes, a knife to cut the sacrament bread, 2 Ink Stands, and a Chamber Pott'.

Building alterations were carried out in 1877-78 by Sir Arthur Blomfield, when the east end was cancelled up a little and the reading desk removed.

Until the 1930's two small domes surmounted the flat roofs on either side of the tower.

The building is Grade 1 listed, status reference 635-1/75/6, dated 29/12/1950, and has an area reference CA/1003/15.

The railings and gate are also listed, Grade 2, ref. 635-1/75/6, dated 29/9/1972.

The Caslon family tomb in St Luke's Churchyard is listed Grade 2, ref. 635-1/75/1, dated 28/9/1995. This is an 18th century chest of Portland stone with a ledger slab of Welsh limestone. It contains William Caslon the Elder (1692-1766) and his son William (1720-1778), who were distinguished type founders, after whom a typeface is named.

The burial grounds are described by Mrs I. Basil Holmes, in her *The London Burial Grounds*, published in 1896, as being "in two parts. The size of the whole ground, nearly 1¼ acres. The piece round the church is closed, and full of large altar tombs, ivy being planted most profusely. There is a great deal of rubbish in it. The part on the north side was laid out as a public garden in 1878, and is maintained by the vestry.

The church was built over a semi subterranean crypt constructed of brick, as an integral part of the church structure. This space was initially prohibited from use for burial but this did not remain the case for long. The Vestry minutes hold no mention of burial within the crypt below the church until 1740, when the fees are listed (see p 56)

Figure 9 Elevation of west end of St Luke's church

By 1810 the vaults were being described as large and commodious but dark, damp, neglected and highly offensive. Sufficient ventilation had not been secured and wooden coffins, rather than lead, had been admitted. The Committee recommend that funerals of opulent inhabitants should be promoted in the vaults and churchyards; that the fees for interment in the vaults and churchyards should not be enhanced, that hereafter no corpse be permitted to be placed in the vaults except in leaden or metal coffins and that apertures should be made in the walls at the east and west ends of the church, of 3 feet in diameter to ventilate the vaults.

In 1853 the Vestry Minutes record that a petition to Viscount Palmerston, Prime Minister at the time, for an extension of time for closing burial grounds and vaults of this church was turned down: burials (including those in the vaults) to be discontinued at the end of this year and the vaults sealed.

The sealing of the vaults was usually carried out by infilling with dumps of soil, domestic refuse and building rubble.

The crypt covers an area of approximately 430m<sup>2</sup>, the floor level being at 17.58m OD. At present it is sealed for safety reasons and access was not available to carry out any observations on the current status of the vaults.

Observations by Dr Susan Young and Simon Coe within the crypt before it was sealed suggest that an amount of vandalism has taken place and that some of the burials have been disturbed. The southern tunnel of the vault has no burials within it.

The floor of the crypt would have been earth and burial had taken place below floor level, to what depth is unknown. In August 1964 instructions were received from London Diocese to remedy damage and secure coffins after disturbance caused by people entering the crypt. It was intended to place them at the east end of the crypt and seal the openings with brickwork. The London Necropolis Company was to be employed in resealing and casing the human remains and handling the coffins to be moved.

From a preliminary shallow excavation it became clear that the task was going to be much bigger than expected, in that once the coffins in the disturbed area were removed to side vaults another layer of coffins would be revealed beneath them. The Necropolis Company estimated that the earth floor of the crypt might cover three layers of coffins spread evenly over the whole area. It was agreed that disturbed coffins should be returned to their original position, while the others were to be left and the areas where the coffins were found was to be completely sealed off.

Much of the crypt has been backfilled with earth, all the coffins being covered. As this is the case it is not known how high the coffins are stacked within.

It has been suggested by Simon Coe that much of the spoil in the crypt is from the clearance of the churchyard area north of Mitchell Street in 1937, and that human remains from there are included within it.

Figure 10 Elevation of South side of St Luke's church

## The Parish of St. Luke's, Old Street

The London watchmaking trade had located its construction sector within the parish of St Luke's and the adjoining Clerkenwell around the middle of the 18th century. By the end of the 18th century the watchmaking artisans in St Luke's were estimated at 1,000.

In the 18th and early 19th centuries many of the poorest in London were Irish. Francis Place, commenting on a description of the 'dissolute manners' of the Irish in St Giles in 1816, says,

'...this account is no doubt correct, and is a fair picture of the manners of a much larger proportion of the people half a century ago. Such people ... are now only to be found in a few places, such as the back settlement of St Giles, some places in the parish of St Luke and Ratcliffe Highway, and almost wholly among the Irish. The poorest and most dissolute people in Spitalfields are several grades above the mere Irish'.

The parish was 'laid out in numerous streets and squares, covered with buildings in every direction, and has become one of the most extensive and populous parishes in the suburbs of the metropolis' according to Lewis, writing in 1840.

In 1798 the Commissioners for Assessed Taxes was established. This divided houses into 5 categories, depending on the total amount of assessed tax they paid each year. This cannot be directly related to annual income but as some tax collectors added additional notes it can be equated.

Cat.	Tax	Ann. Income
I	Under £1	£61
II	£1-Under £2 tax	£66
III	£2-under £5 tax	£79
IV	£5-under £10 tax	£128
V	£10 tax and over	over £200

Old Street parish had only 16.6% of cat IV & V houses and could therefore be classed as a poor parish, all the parishes within the City had over 50%.

Further information about the parish can be obtained from the Vestry Minutes, which at this stage have only been studied for references to the crypt and burials, and many other available sources should any excavation be carried out.

## Archaeological Work from the Vicinity of the Site

### 76-78 Old Street (OLD89)

A series of test pits were observed, which showed post-medieval dumping and medieval stratigraphy overlying brickearth. The majority of the pits were too shallow to reveal the full extent and nature of the archaeological survival on the site.

### 125 Golden Lane (GOL90)

During excavation a block of dressed sandstone, provisionally Tudor pottery and a post-medieval yellow-glazed tile were found and layers containing small greensand fragments were observed.

### 198-208 Old Street (ODS92)

Extensive areas of 17th century brick quarrying were exposed during an archaeological evaluation. Large landfill deposits were found which included remains of industrial processes as well as domestic rubbish and building rubble. These deposits had been cut through by 18th century features, including several walls and a well containing several whole wine bottles, porcelain, and eastern influenced European tin glazed ware. These may be the remains of St Luke's workhouse. 19th century structures were also recorded.

### 122-128 Old Street (OLS94)

An archaeological deposit was found along the east side of the site, which was probably late 17th century landfill dumping, carried out as part of a large landfill event.

### St Luke's Estate (BAH96)

Probable boundary walls for the cemetery of St Luke's poor ground, known as the Pest House Ground, were recorded in an attempt to define the limits of the cemetery. A large quantity of disarticulated human bone was observed, probably from a charnel pit. Articulated remains were seen in the trench sides.

## Archaeological Potential

### Prehistoric

Palaeolithic artefacts have been found within the vicinity of the site. These are rare and any discovery is consequently very important but equally, unlikely to occur, as they are usually represented in this area by stray finds.

Finds, considered to be of Iron Age date, have been recovered in Golden Lane, to the south-west of the site and Old Street may be part of a pre-Roman traffic route. However, if Iron Age material is present on the site it is also likely to be represented by stray finds.

### Roman

Old Street is considered to be part of a Roman road and gravelled surfaces with stratified Roman coins were revealed in Victorian sewer excavations during 1867. No settlement activity is known from this area, nor is it within a known burial area. Roman material has been found within the area of the site, but it is unlikely that more than occasional finds.

### Medieval

The land occupied by the church during the medieval period was mainly used for agriculture. There is an SMR reference to a medieval manor house for the church site, but as explained earlier this must be regarded as suspect. A house has been built on the site by the 16th century (see figure 3) and it is possible that traces of this remain.

### Post medieval

There is a low potential of any archaeological remains surviving below the floor level of the church crypt. This is at 17.6m OD and has had burials cut into it to an unknown depth. Excavations 120m to the south-east of the site at 122-128 Old Street showed a 17th and 18th century landfill dump between 18.76m and 17.40m OD, with naturally deposited brickearth at around 15.1m OD, although this was in areas truncated by 20th century activity.

The test pit report, (see appendix 2) did not reveal any archaeological deposits which were demonstrably earlier than the church although a hard gravel surface, which may have been contemporary with its construction, was recorded at 16.75m OD.

It is possible that the subsidence on the north-east quarter of the church has been caused by quarries and fishponds dating from the late medieval period known from the vicinity.

The main archaeological implication for this site are the burials within the crypt and any areas of the churchyard that are to be disturbed.

Very little in the way of systematic recording of crypt burial populations has occurred. While several clearances have been conducted at London churches, to date, only Christ Church Spitalfields has been subject archaeological and osteological recording. This was carried out in tandem with documentary research on the individuals interred within, who could be identified from coffin plates.

Work carried out at St Luke's could be used to act as a control for the Christ Church material. Additional biological material is required to corroborate the methodological and demographic findings of the Christ Church project. The high percentage of Huguenot burials at Spitalfields means that a less ethnically specialised group is required. The crypt population of St Luke's is contemporary to Christ Church and probably more representative of the indigenous population.

The nature of the burial records for the church need to be looked at. At Christ Church, no cause of death is given in the burial register, so no cause of death can be assessed prior to the beginning of civil registration in 1837. Therefore, of the 389 named burials excavated the cause of death could be determined from the records in only 28 cases.

At St Luke's, the burial registers include cause of death from their commencement in May 1733 through to the introduction of pre-printed forms at the end of December 1812. Therefore with the civil registration death certificates, cause should be available for around 90 years of the crypts use.

This may allow different aspects of osteological research to be tested and evaluated, including observable pathologies and the correlation between disease and skeletal remains.

There are, however, many cases where the cause of death is difficult to deduce from the 19th century diagnoses listed in the registers. In five cases at Christ Church of the individuals with death certificates, it was considered that there should be skeletal pathologies reflecting the conditions mentioned, but in no instance was this the case.

For the majority of the time the burial registers do not include a location of burial so no determination of the number of burials within the crypt can be obtained from this source. The period for which location of burial is available gives a figure of around 4 to 5 burials per year. If we assume that burials commenced in 1740 and finished in 1853 this would give a figure of between 450-570 individuals within the crypt.

At Christ Church there is a steady increase in the number of burials up to the peak period in the 1820's, which was followed by a decline, particularly after 1840. This may be due to local factors and not reflected at St Luke's.

The Vestry Minutes do survive for the period of use of the crypt and these have at present only been scanned for mentions of the crypt and vaults. These may well include further information relating to the individuals interred within, while the wide range of other available documentation available includes tax returns, census returns, insurance policies, trade directories, company records, wills and probate records.

The continuing study of funerary practices and their relation to the populations could be advanced considerably by the chance to look at another crypt group.

It should not be forgotten that the church is a significant building in itself. The chance to carry out archaeological excavations adjacent to the foundations may well give a good idea of the construction methods used and possibly the sequence of building. The recording of the crypt area under the church should be carried out as part of any works carried out.

It is clear from the consultations carried out by the author that some disturbance of the crypt has taken place. Without access to the crypt it is not possible to determine to what extent this may have damaged the archaeological integrity of the site. The higher the level of disturbance the more likely it is that coffin plates will have become detached from their appropriate context, and that therefore a much lower percentage of named burials can be obtained.

The disturbances within the burial area will also have adversely affected the environmental conditions. A sealed crypt has a relatively stable environment, with temperature, soil moisture and humidity levels unlikely to have significantly altered since the sealing date. These factors can seriously affect the preservation of the material within the crypt, particularly coffin wood and fittings. An evaluation of the current state of preservation is not available at the time of writing, as access to the crypt has not been possible.

The skeletal sample excavated from Christ Church crypts provided one of the most important collections ever recovered from Great Britain, but this does not mean that research should stop.

A sample size of 389, when broken down into sub-groups for specific purposes, is too small usually to be statistically valid, or to give anything other than an indication of specific factors.

If work is to be carried out in the external burial grounds some disturbance to graves is likely to occur. Articulated burials were observed close to the church walls in the recent test pits and the presence of disarticulated bones suggests disturbance to other graves, probably caused by 19th and 20th century remedial works to the church.

Extra mural brick burial vaults were also observed in the test pits and it is likely that more of these are present. It may be possible to determine the positions of these from the information once it has been decided where any work is to be carried out.

The work to be carried out if the cemeteries would provide an excellent opportunity to compare groups within the crypt and their external contemporaries. These should be looked at in any case, assuming a reasonable sample size, as part of the ongoing research into London's population.

### Information generally available from skeletal analysis.

Although information to satisfy the following points would be obtainable from most collections of human skeletal remains, it is still necessary to continue to cover more samples as they turn up as the ultimate goal is to build up a picture of London's population at all strata of society and throughout all periods. An end result of the analysis more immediately relevant to the site itself is that human remains provide the most direct evidence of what people buried at that site were experiencing during life. The data collected for this analysis should allow comment on the following points.

#### 1. Demography

A probable age and sex can be assigned to each individual. The demographic composition of this site can then be compared to those known for contemporary sites and sites of a similar type but different period. Any dissimilarities or unusual features in the site composition revealed in this way may highlight differences in behaviour, burial ritual, attitudes to the dead and so on at this site compared to others. For example, segregation of children from adult burials is quite commonly found and this would be demonstrated by spatial analysis of the burials revealing groupings of specific ages rather than a general mix. Demographic comparisons can also allow inferences about the lifestyle of the people. It can pick up such features as high infant mortality which, in conjunction with other indicators can allow inferences about the environment and general state of health and hygiene.

#### 2. Social status

Higher status in some individuals than others can be inferred from a combination of indicators. For example, when such features as general attainment of the maximum stature for that sample is found in one group of burials when the rest of the sample is more variable or the absence of indicators of nutritional deficiency are found in clusters when the same indicators are widespread in the rest of the sample, may indicate an area of higher status burials. As more characteristics of this type are found in combination the suggestion gains strength. Segregation of certain types of pathology may target people with specific ways of life, for example, diffuse idiopathic skeletal hyperostosis appears to be increasingly linked to those burials thought to represent the more affluent sections of society. Chemical analysis of the bone can comment on diet and, in turn, on status. Strontium has been used detect meat rich diets which is often interpreted as indicative of elevated status.

#### 3. Environmental factors and health of sample.

The presence of certain pathologies may allow comment on the environment of the people, for example, nutritional deficiencies have an effect on the bone while certain pathologies require a population pool of sufficient size to thrive. The accepted level of hygiene could be inferred from the standard of dental hygiene or from the amount of parasites found in soil samples taken from the burials where preservation of them is favourable.

Iron deficiency in life can be detected by low levels in bone samples or by changes it causes in the bone itself. Industrial practise may affect the skeleton either by repetitive actions causing skeletal modification or by the ingestion during life of industrial substances, such as lead, which may show up in chemical analysis.

#### 4. Community organisation.

In addition to the information already discussed for social status or attitudes to different sections of the community as expressed by burial organisation, evidence of codes of conduct such as altruism in the community can be inferred from the reaction to various pathology. Sufferers of severe pathologies, such as spina bifida, may not survive without a measure of care from others. Well healed trauma with no sign of infection may suggest care of some kind. Reduced fractures of limbs which otherwise would have healed out of alignment, suggest treatment of some kind. Evidence of any of these would suggest some element of community organisation where every member is not simply fending for themselves.

#### 5. Genetic relationships and racial types.

Spatial analysis of non metric traits may reveal clustering of suites of traits. This has been used to suggest the close genetic relationship of certain burials and would be especially interesting in order to investigate the composition of grouped burials with regard to family groups or otherwise. Patterns of differences in cranial and post cranial indices calculated from measurements on the skeleton have been used to suggest the presence of different racial types. If the presence of people of different racial type could be reliably established, their occurrence could be analysed spatially and through time with reference to the archaeological data in order to investigate any segregation of racial groups within the cemetery or changes in the racial composition of the sample over time. This is especially important in a city like London which has always been subject to migration in from outside.

#### 6. Spin-offs.

Study of the bone invariably provides data for other disciplines at no extra cost. Information of great interest to the medical community may be gained about the antiquity of certain diseases. Differential preservation of bone across the site may contribute to the understanding of taphonomic processes. This is of great value as experiments on the effects of different conditions on the preservation of human bone are not permitted so this is the only way information can be gleaned. Efficiency of recovery of parts of the skeleton can be examined and this can help to increase the efficiency of future excavations or safeguard against unreliable conclusions based on a biased sample.

## Health and Safety Implications

Excavation work in burial vaults introduces a whole range of health and safety questions not usually encountered in archaeological work. These include the risk of infectious diseases, post traumatic stress disorder, problems caused by moving and lifting heavy objects and of heavy metal contamination.

The possibility of survival of soft tissue within sealed lead coffins introduces the danger of infectious diseases. Of these the one to which most attention has been paid is smallpox.

Smallpox is considered to have been eradicated world-wide, Britain having been relatively free of the disease since 1935, with the last case being in 1978. Compulsory vaccination ended in the 1950's with some vaccinations continuing into the early 1960's. Very few vaccinations were carried out after this time.

It has never been proved that smallpox can remain viable in the soil, nor has it been shown that the virus can be regenerated. It has been suggested that that smallpox may persist in the environment under natural conditions and anecdotal evidence has been collected to suggest that it may be transferred through the disturbance of human remains. Although viable smallpox viruses may persist in bodies buried in permafrost, the dried scabs detected on a semi-desiccated body at Christ Church, Spitalfields in 1985, were eventually declared non-viable. Despite the negative result the Health and Safety Executive decided that all staff had to be inoculated against smallpox, which could only be carried out on individuals with primary inoculation scars.

MoLAS has long operated on the principal that only primary inoculated staff are eligible to work on post-medieval burial sites, even when the possibility of soft tissue survival is almost none.

Anthrax spores can survive in dry aerobic conditions and might be located in sites where animal products were handled. It was, however, not a common cause of death after the end of the 18th century, particularly not in an urban context. Humans are moderately resistant to anthrax, which can be cured with the use of penicillin, although the risk of releasing the bacillus from buried soils is considered minimal, as the pathogen only spores when open to the air.

A further problem encountered at Christ Church, Spitalfields was the increase in lead/blood levels in staff working on lead coffins. These levels rose more rapidly when sealed lead coffins were opened on a daily basis. Precautions were taken to avoid contamination through the use of the recommended PPE. However, as levels continued to rise when staff were working on the site, it was concluded that the cause was the concentration of lead in the atmosphere.

The handling of wooden coffins may introduce the possibility of pathogenic fungi or insects feeding on decaying wood. In one case at Christ Church an unidentified skin disease was contracted by a member of staff which was tentatively linked to these causes.

The nature of the archaeological material in a crypt, in particular lead coffins which can weigh up to ¼ tonnes, introduces a higher danger than usual of lifting and carrying injuries.

Archaeologists, in general, have little or no experience of dealing with preserved human remains. Opening sealed coffins and anticipating what may be inside, as well as exposure to the processes of autolysis and putrefaction can cause post traumatic stress disorder (PTSD) in some individuals. Consultation with experts in the field would be required before any work commenced to determine the best working practices to minimise stress to the workforce.

At Christ Church, Spitalfields the restricted environment of the crypt, in combination with the nature of the work led to reduced physical and psychological immunity. Constant monitoring of the health of the workforce would be required for the duration of any work carried out in the crypt.

Negotiations and liaison with the Environmental Health Department of the London Borough of Islington are essential before any work commences and must continue for the duration of the project.

Discussions with Simon Coe of Biscoe and Craighall, who are surveyors acting for the Church Commissioners, introduced the problem of the structural integrity of the church building.

The burial vaults, constructed of brick, are an integral part of the church structure and the church will collapse if the vaulting is removed. However, the vaults must be removed as part of any new development to stabilise the rest of the structure, which is subsiding and in danger of collapse, particularly the north-east corner of the church, which is not underpinned.

The information received is that the vaults themselves have been damaged by the general neglect of the church and by serious vandalism problems, which has left them in a very unstable condition and unsafe to work in. The burials within the crypt must be removed before any redevelopment of the building can occur, but the vaults do not appear to be supportable with the burials in place while the area is too unsafe to work in to remove the burials.

While the engineering problems this engenders are outside the scope of this report, it should be noted that this appears to have serious implications for any archaeological work within the crypt.

The legal requirements for the removal of the burials in both the crypt and external churchyard will need to be observed.

A Burial Licence, under the terms and conditions of the 1857 Burial Act, Section 25 is required.

It is a condition of this licence that the following precautions are observed;

- a) *The removal shall be affected with due care and attention to decency;*
- b) *The ground in which the remains are interred shall be screened from the public gaze while the work of removal is in progress;*
- c) *The remains, if of sufficient scientific interest, be conveyed by a suitably qualified person under the arrangements of The Museum of London.*
- d) *The remains shall, if of sufficient scientific interest, be conveyed to a museum for archival storage under the arrangement of the above, or they shall be conveyed to a place where burials may legally take place and there be reinterred.*

The Disused Burial Grounds Act of 1884 states in section 3:

*It shall not be lawful to erect any buildings upon any disused burial ground, except for the purpose of enlarging a church, chapel, meeting house, or other places of worship.*

The Disused Burial Grounds (Amendment) Act of 1981 states that:

*1. -(2) Notice of any proposal to erect a building in which human remains are interred shall be given by or on behalf of the church or other religious body by whom or on whose behalf the land is held by-*

*a) advertisement in two successive weeks in one or more newspapers circulating in the area where such land is situated, and*

*b) notice displayed on or near such land*

*specifying the time (not being less than six weeks from the date of the first publication of the newspaper advertisement) within which and the manner in which objections thereto can be made.*

*2. -(1) Where any human remains are interred in such land no building shall be erected upon it otherwise than in accordance with section 3 of the principal Act unless:-*

*a) the human remains have been removed and reinterred or cremated in accordance with the provisions of the Schedule to this Act; and*

*b) any tombstones, monuments or memorials commemorating the deceased persons have been dealt with in accordance with those provisions*

*and the other requirements of the said Schedule have been complied with in respect thereof.*

Ideally, the human remains should remain undisturbed, preserved *in situ*, both in the crypt and the churchyards. However, if the pressure of the proposed development is such that this is impossible, then a mitigation strategy must be determined.

The legal requirements are such that the clearance of the burials must be carried out before the proposed development can proceed. The method of this clearance needs to be considered alongside the archaeological implications of a buried crypt population.

In order to develop the information recovered from Christ Church Spitalfields more skeletal material for which biographical details are known is required.

For that reason alone, if the crypt is sufficiently undisturbed to obtain a reasonable named sample, then, the burials become of national importance. Too much of this material has been cleared in the past, with no archaeological or anthropological recording having been carried out. This is still the case right to the present day, with both crypts and cemeteries continuing to be commercially cleared.

As the resource is diminished the opportunities to carry out an archaeological excavation on a crypt population are receding. The health and safety requirement to use only staff who have had a primary smallpox vaccination introduces the need to form an excavation team by basis of age. The increasing age of the vaccinated archaeologist contrasted to the usual age of most digging teams means that there is a finite period of time in which projects of this kind can be carried out.

Unfortunately, as access to the crypt was not possible it has been difficult to gather a full picture of the present state of the structure and its contents. It is, therefore, very difficult to evaluate whether the recorded interventions by vandals and by the remedial works needed to stabilise the church have caused a lot of disturbance to the burials. If this is the case then it is likely that coffin plates will have become detached from the burials to which they relate, which reduces the number of named burials obtainable. It may well also reduce the level of preservation of soft tissues within the crypt.

The character of burial within the crypt appears to include both placement within the vaults and burials in the earth of the floor. The preservation of human remains within coffins does not generally correlate to either the type of coffin or its state of preservation, and it seems reasonable to assume that the remains will vary between completely skeletal remains and reasonably intact cadavers.

The documentary records for the church and parish are fairly comprehensive. The burial registers exist for the whole period of the use of the crypt. For the majority of the time these include cause of death, along with the address of the deceased from 1804 onwards. Place of burial is included for too short a period of time to use this as an evaluation of the number of burials in the crypt.

Burials from the churchyard are also important as part of the ongoing study of London's population from its skeletal remains. It is quite possible that, if the ground is as damp as the subsidence of the church suggests, coffin wood preservation may be good. This is unusual in earth burials and may allow good survival of coffin fittings, including coffin name plates. 0200

The church is an historic building and the crypt below is an integral part of it. It should be recorded both as a standing building and archaeologically.

Further archaeological work is likely to be required as part of the development work on St Luke's Church. Once the engineering problems have been solved and a development plan determined then a programme of archaeological work can be determined, in consultation with English Heritage, based upon the impact of the development on the archaeological remains.

At this stage, serious consultation with the many concerned bodies needs to take place, specific research objectives determined and a project design produced, taking into account the various factors involved in a complex, multi-disciplinary undertaking.

## APPENDICES

- 1 Historical Documentation
- 2 Test Pit Report

There are four potential sources of information:

1. Published material
2. Church burial registers
3. Vestry minutes (recording decisions taken by the vestry concerning the administration, financing, fabric and maintenance of the church)
4. Bishop's or other faculties (permissions given by the diocesan or other (in this case the Dean of St Paul's) for significant alterations, repairs, rebuildings etc. in response to a formal petition from the incumbent and vestry)

The present assessment has found:

1. Published material

Nothing of value, or failing that not even a church guidebook

2. Burial registers

These are held, with baptismal and marriage registers, at the Greater London Record Office, where they are available only on microfilm (Films X27/1A, 1B, 2, 13-15).

Arranged in monthly, or part monthly, blocks interspersed with sections for christenings and marriages. The format is: name; man/woman/child (*not* age); cause of death (e.g. consumption, ague, dropsy, smallpox, 'age'). Variable legibility on account of hand-writing but mainly low photographic contrast. There is no indication of place of burial until 1804 when exact ages and addresses of deceased are also introduced.

Apart from a 16-month gap between August 1805 and December 1807 this system lasted until December 1812, after which it was replaced by printed register pages which did not require information of this kind. Places of interment are indicated by codes: NBG (presumably 'north burial ground'), SBG ('south burial ground?'), PHG (? Pest House ground?), BCY (? 'Back Church Yard'), FCY (? 'Front Church Yard') and 'Vault'.

In the period 1804-5 and 1807-12 there were eighteen vault interments. The commonest causes of death in these were consumption and convulsions, and there were also cases of dropsy, death in 'childbed', and 'shot himself' (presumably unintentionally and not a suicide).

No Searchers Reports or Burial fee books, which could have provided comparable information for the years before 1804 and after 1812, appear to have survived at the GLRO, Finsbury Library or Guildhall Library. CLRO

The GLRO does however hold a *Register of headstones in back church yard c 1753-1855*: records inscriptions on stones, name, person or family and plot number (Film X27/16); and *Monumental inscriptions in St Luke's Church Yard*, with index (1877). Described as similar to that for the Back Churchyard [and therefore presumably concerning the front churchyard]. (Film X27/18). (Cf. Faculties below)

### 3. Vestry Minutes

These are held at the Finsbury Local History Library and have not been consulted as part of the present assessment since at best they would provide only spasmodic and incidental information relating to burials in the vaults or elsewhere. According to the Librarian at Finsbury there is also a record of the stones and a plan of their location (after removal, not before) made c 1937 when the graveyard was cleared and the stones relocated against the walls of the church (cf. Faculties below).

### 4. Faculties

The indexes of the diocesan Vicar General's Act Books at Guildhall Library MS 9532/4-10 (1725-1826) have been checked: neither St Luke's nor St Giles's is mentioned, so that the church must have been subject to the St Paul's Dean and Chapter in this respect. This has been confirmed by checking the St Paul's faculties (also at Guildhall Library) up to 1796 (MS 25,664/3-5). However they relate only to appointments of clergy etc. From the 1840s St Paul's faculties were absorbed by the diocesan system.

At Guildhall Library only the faculty papers from 1870 have been properly sorted and indexed (before that date only the faculties themselves are given in the Act Books, as above, without supporting petitions and papers).

# ST. LUKE'S, OLD STREET

## Documentary Research

Tony Dyson

Oct 1996

Parish formed from St Giles Cripplegate in 1733; recently reunited 1959-79 with St Giles, 'where current records are held', though nothing of relevance with St Giles material at Guildhall Library.

## GREATER LONDON RECORD OFFICE

### Burial registers October 1733 - June 1854

Originals 'unfit' and not producible. Available in the form of :

Microfilms X27/1A, 1B, 2, 13-15.

/1A (May 1733 [sic] to 1747)

Arranged in monthly, or part monthly, blocks interspersed with sections for christenings and marriages. The format is: name; man/woman/child (*not* age); cause of death (*e.g.* consumption, ague, dropsy, smallpox, 'age'). Largely illegible (because of low contrast) for much of the 1740s. But no indication of where buried.

/1B (1747-1776)

The same format, unchanged. Legibility intermittently worse, this time compounded by variable handwriting. Again, no indication of place of interment.

/2 (1776-1809)

Similar format; good condition and legibility at beginning deteriorating a little towards the end.

From July 1804 a reversion to the inclusion of addresses and place of interment. No explanation of codes on introduction. 04200

NBG

SBG

PHG (? Pest House Ground, though only one case obviously infectious)

BCY

FCY

Noting of place of burial suspended August 1805, resuming in December 1808.  
Dropped again March 1809.

Vault convulsion

Vault childbed

Vault convulsions

Vault consumption

Four vault burials in period July 1804-August 1805 (12 months) NB entries from December 1807 duplicated in:

/13 (1807-23)

Begins December 1807 has a much smaller format, with headings for name, address, age (in years), cause of death, and date of burial, but also a system of codes:

NBG (?North burial ground)

SBG (?South burial ground)

['Pens' often included in this column but presumably denotes 'pensioner' (and often run on from the address 'workhouse'). Not obviously relevant to location of burial, though it could be a euphemism for a pauper burial]

But also: NBGP

PHG

BCY BCYP, FCY, FCYP (? 'Back Church Yard', 'Front Church Yard' and 'Front Church Yard P', and (but only very rarely)

SBGP

Vault P

Vault P ii

P, except in the case of vaults, may stand for 'Pauper'.

Vault mortification  
 Vault consumption  
 Vaults consumption 21 April 1810  
 Vaults age 5 Nov 1810  
 Vaults consumption 18 Feb 1811  
 Vault consumption 13 July 1811  
 Vault childbed 18 Oct 1811  
 Vault water on the brain 22 Dec 1811  
 Vault consumption 24 Dec 1811  
 Vault cause not given 18 May 1812  
 Vault shot himself 15 July 1812  
 Vault dropsy 18 Jul 1812  
 Vault age 17 Aug 1812  
 Vault dropsy 22 Oct 1812

Register ends 29 December 1812, followed by printed format from January 1813

So 14 burials in five-year period December 1807 to December 1812, plus four from 12 month period July 1804 to August 1805: i.e. July 1804 to December 1812, except for 16 months from August 1805 to December 1807

In January 1813 new printed, pro forma registers were introduced that cater only for name, 'abode', when buried, and 'by whom ceremony performed' but not for location of the burials. Nor was the information added within existing columns, though there was ample space to do so. This system was still in use in 1841-54 (Film /15).

Also:

*Register of headstones in back church yard c 1753-1855:* records inscriptions on stones, name, person or family and plot number (Film X27/16)

*Monumental inscriptions in St Luke's Church Yard,* with index. Volume similar to that for the Back Churchyard. 1877. (Film X27/18)

## FINSBURY LIBRARY

has nothing in the way of vestry minutes for the church (as distinct from the parish); only a record made in 1935-6 on the removal of gravestones from the (external) burial grounds, with inscriptions and plan of sites. No burial fees, searchers reports.

But existing vestry minutes may have details of graveyard clearance c 1935-6. Stones moved against the church, and bodies almost certainly cleared (photos of work in progress). There is a record of the stones, and a plan (though not apparently of original position of the burials). The site in question lay between Ironmonger Row on one side; Helmet Row on the opposite and a third side, and an 'entrance'

[Ironmonger and Helmet Rows run N-S the whole length of the church grounds. But Mitchell Street runs E-W at the N end and Old Street E-W at the S end. So it looks as if the plan covers only one E-W slice of the grounds as a whole]

Church closed and demolished, except for tower, in the first half of 1960. Effects transferred to St Giles Cripplegate.

## GUILDHALL LIBRARY, Dept MSS

Strong probability that when St Luke's records were transferred to St Giles' in 1959-79 they in fact ended up at GL along with the St Giles records proper. In fact they didn't, though there are records of joint administration of parish estates, charities etc. from 1830s and 1860s.

There is a collection of parish papers for St Luke's (GL MS 19224/376) but this contains details only of the parsonage house and parish property in Essex.

## Bishops' Faculties

Vicar General's Act books MS 9532/4-10 (1725-1826) seen: neither St Luke's nor St Giles' mentioned, so apparently a 'St Paul's' church.

1877 Underpin south and east walls and major repairs, MS 18,319/86

14 March 1877: Faculty to alter and improve the parish church: underpin S and E walls and pier supporting the E column on the S side... the resealing of the whole of the ground floor of the church according to the plan annexed. At the same date a petition of the laying out of the churchyard as ornamental gardens: removal and setting back carefully of such memorial stones as may be necessary for the construction of pathways... that none of the bodies or remains will be removed from the churchyard.

1937 List of tombstones in disused burial ground /101

This item was called back from GL by the Diocesan Register, who have retained it.

1946-9 LCC to maintain and develop churchyard)

/113

1949 Layout of churchyard as gardens )

Petition granted for laying out the southern part of the burial grounds in the manner shown on the plan. Earlier works of the kind previously carried out by the LCC. To lower tombstones and cover the area with soil to level up; in the place of brick vaults to reduce the brickwork and replace the top slab and cover with soil. Also references to work on the 'rear portion' beyond Mitchell Street. Only tombstones in 'bad' condition to be moved.

1960 Re dangerous structures, notice /162

Faculty granted 1 June 1960 for demolishing the church except the tower to ground level as a dangerous structure, and removing scheduled items to St Giles. Removal of tablets to the tower. Nothing said about the vaults. Schedule of memorial tablets (of which only a few).

**1965: Transfer of burial ground and pest house (GL MS 29441/376/1)**

A Faculty to enable the GLC to exercise powers of management under the provisions of the Open Spaces Act 1906 in respect of St Luke's Pesthouse burial ground. Involved 'conveyance' of the burial ground from the incumbent to the GLC subject to the preservation of existing monuments, if any, for the sum of £7,500. The Council agreed to lay out the burial ground as an open space within the meaning of the Act.

No indication is given of the site of the Pest House and burial ground.

00000

**1975: Redevelopment of churchyard (GL MS 21544/376)**

Letter of 17 July 1975 from the Islington borough solicitor to the Diocesan Registry noting that the Council was considering the inclusion of the former church and churchyard of St Luke in a plan for the proposed Finsbury Leisure Centre, and that he has been advised that a Faculty is required before the intended work can be carried out to the north of the footpath between Mitchell Street and Ironmonger Row, which is consecrated ground. Possible uses include a blind garden or a bowling green, it being understood that no building was permissible. Could the Registrar please say whether or not the Chancellor would be likely to object in principle.

The Registrar replied on 29 that the Chancellor has no objection subject to the Diocesan Burial Grounds Act and the advice of the Diocesan Advisory Committee.

**1964-5: Reinterment and bricking up of vaults (GL MS 29441/376/1)**

A petition from the rector dated 27 November 1964 concerning the unlawful entry of thieves and tramps into the roofless precinct on many occasions since the partial demolition of the nave. While blocking windows and building up openings in the brickwork etc. in July it had been found that coffins had been disturbed and in one instance the lead interior had been taken apart from the case and the top forced off to reveal the human remains in an advance state of decay. These were immediately sealed in a zinc coffin. The name plate removed from the damaged coffin was inscribed: 'Mrs Esther Tomkies, died 2 December 1953 [sic] in her 53rd year'. A builder has placed an estimate of £77 as the cost of bricking up the remaining openings into the crypt to prevent further vandalism. This would deter attempts to gain entry into the crypt from basement level, and work already done in July 1964 [no faculty appears to be available for this] should in turn deter attempted entries from ground level.

A plan of the crypt and vaults showing the position and bricking up of the remaining openings is hereto annexed and marked 'B' (see figure 11)

Permission requested to confirm placing of the remains in a new coffin to remain in the same position as the old one, and to authorise brickings up.

A memorandum by H Norman Haines, Diocesan Architect at Fulham Palace, dated 10 November 1964 helpfully makes clear that Mrs Tomkies died in 1853 not 1953, and notes that the first break in at the church was reported in November 1960 and again in August 1961. Doors were broken down and there had been interference with the contents of the Crypt. The only access to the latter was via the SW porch and staircase, but entry had also been forced through holes made in the nave floor. Similar doings were reported in April 1964 when a thorough search was made of the crypt with the aid of temporary lighting. A further inspection in July, while contractors were bricking up walls and sealing the holes in the floor with concrete slabs, revealed that coffins had been disturbed (as reported by the incumbent).

In August instructions were received from London Diocese to remedy the damage and secure the coffins from further disturbance by placing them at the east end of the crypt and sealing the openings with brickwork. The London Necropolis Company was to be employed in resealing and casing the human remains and handling to the coffins to be moved out of harm's way.

From a preliminary shallow excavation in August 1964 it became clear that the crypt task was going to be much bigger than expected, in that once the coffins in the disturbed area were removed to side vaults another layer of coffins would be revealed beneath them. The Necropolis Company reckoned that the earth floor of the crypt floor might cover three layers of coffins spread evenly over the whole floor area.

All involved according agreed that the open coffin should be returned to its original position when 'dealt with', the others to be left as they were and the areas where the coffins were found to be completely sealed off.

On 13 November 1964 the Registrar reported to Haines at Fulham Palace that the bricking up of the four openings into the crypt had now commenced [NB that Plan 'B' only colours in two blockings, though the position of the other two seems pretty obvious: at the foot of the northern staircase and between the second and third chambers]

#### 1989-91: Removal of human remains (GL MS 29441/376/2)

On 8 March 1989 an application was made for a dispensation order for leaving undisturbed human remains under part of St Luke's churchyard which was to be used as a car park, and for their removal under part of the churchyard, edged orange on Plan A, where an extension of the church was proposed, and also for their removal from the crypt. All removed remains were to be reinterred in the part of the churchyard marked blue.

[The plan shows that the orange area, the site of the offices, lay directly north of the east end of the church; and the blue area was the part of the churchyard south of the church between Helmet Row and Ironmonger Row. The whole of the church site itself is coloured green. The intention seems to have been to sell the church site to the Pattenmakers as the location for their proposed livery hall: the office extension in the churchyard to the north was part of this scheme]

On 28 April 1989 chartered surveyors informed the Diocesan Registrar that 'within the crypt the coffins and remains are covered by an earth fill and therefore, as yet, are inaccessible'.

OJES

On 20 July 1989 the Home Office informed the Diocesan Registrar notes that the Secretary of State had issued directives for the removal and reinterment of human remains from the church (area coloured green) and the part of the churchyard marked orange.

Much argy-bargy between the Home Office and the Registrar early in 1990 about whether the church, and which part of the churchyard, was to be included in the dispensation, or whether they should be covered by other provisions.

[Seems pretty clear that a mistake had been made with the application but were trying to get the Home Office to accept it all the same. But the Home Office kept on insisting as politely as they possibly could that the application and subsequent comments about what was meant in it were confusing and ambiguous.]

On 26 March 1990 the Registrar asked the Home Office to omit any reference in the dispensation order with regard to the crypt, feeling that it would come under the provision of earlier directives given by your office.

On 17 August 1990 Home Office sends Registrar a new draft dispensation order covering the entire area except the two areas where remains will be disturbed: the churchyard area in orange (for the office extension) and the church itself.

On 27 September the Registrar notified the Home Office that the order was correct as drafted, and asked for the order to be issued.

On 9 May 1991 the Home Office wrote to the Registrar enclosing the dispensation order (dated 8 May), excluding the areas bounded by thick orange and green lines.

Diocesan Faculties Register MS 9532, from 1685 to 1870s (thereafter Faculty papers in good condition, and indexed on cards).

St Paul's faculties .

MS 25,664/3-5 ( - 1796)

seen. St Luke's covered but only in re appointments

MS 25,738 run from 1833

GUILDHALL LIBRARY, Printed Books

Not even a church guide

Adams and King, *The historie of Eald Street now called Old Street with memoranda of the parish of St Luke* [nd, c 1860]: unpaginated. Reference to a statute of 'George II c.21' forming St Luke's as a separate parish. The church finished in 1732 and consecrated on St Luke's day [18 October] 1733. Living in the gift of St Paul's.

Nicolas Adam, 'A Hawksmoor church in danger' (*Illustrated London News*, vol. 262 (1974) June, p 74). Roof removed in 1960 (which would have been when the parish was reamalgamated with St Giles' and records transferred). Quotes architectural consultant who claims that the stated reasons for removing the roof would have applied just as well to the roof of St Paul's cathedral.

No *Survey of London* volume for the parish.

H B Wheatley & P Cunningham, *London Past and Present*, ii (1891).450-1

The church, which had been suffered to fall into disrepair, was restored in 1877-8 at a cost of over £7000; and at the same time the churchyard, of about 4 acres, was converted into a public recreation ground. Caslon the famous typefounder was interred here in 1766; and Thomas Allen, historian of London, in 1833.

### 1) VESTRY MINUTES 1733-1855

#### 1733-1754

p 25 (12 June 1734): a well to be made in the Back Burial Ground to drain the water out of the same.

p 27 (27 August 1734): burying dues in back burial ground south side 13s 6d; middle ground 7s; pensioners at the lower end 2s 8d. Two corpses are not to be buried in any one grave, and the same not to be less than 4 feet deep. [Nothing about the vaults]

p 43 (9 May 1735): ordered that the Pesthouse burial ground be shut up (unhealthful and 'noysance')

pp 60-61 (30 March 1736): references to burial in any of the parish burial grounds [but no mention of vaults].

p 148 (7 June 1739): references to burial out of the churchyards or burial grounds belonging to the parish [nothing about vaults]

p 178-9 (5 December 1740): Burial fees

#### *Payable to Churchwardens for:*

Burial in the vaults under the church £2

Ground on the southern part of the churchyard £1

Ground on the northern part of the churchyard 14s

In the southern part of the burial ground 8s

In the northern part of the burial ground 6s

Pesthouse (pensioners excepted) 3s 6d

Ditto (if under 10) 2s 6d

For every vault to be inclosed under the church to be purchased of the parish at per foot square 3s

For every vault to be purchased of the parish in the churchyard or burial ground at per foot square 4s

#### *Payable to the Clerk for:*

burial under the church, 2s 6d

in the churchyard. 9d

in the other grounds. 6d

*Payable to the Sexton for:*

burial in the vaults 2s  
 in the ground on the south part of the churchyard 2s  
 Ditto on the north part 1s 6d  
 South part of the burial ground 1s 6d  
 Ditto north 1s  
 Pesthouse 1s

*Payable to the Bearers for:*

Burial in vaults to each bearer 2s  
 In each burial ground ditto 1s

[So burials certainly being made in vaults by December 1740, but apparently not before (the new scale of charges of the same date could have arisen from the introduction of burials there as an alternative option)]

p 185 (3 March 1741): Pesthouse behind the garden of Allen's (?Alley'n's) Almshouses

p 215 (17 October 1743): vault made in south churchyard by friends of Mr Wells.

Ordered that in future no person shall be buried nor any ground broken in the church or churchyards or any of the burying grounds belonging to this parish nor any vault shall be suffered to be made nor any gravestone or monument shall be laid down or set up until the friends and relations of the deceased shall have first paid the church dues to the Churchwarden (etc.)

p 306 (20 June 1751): Pesthouse burial ground be shut up till orders to the contrary. Burials in the Back churchyard 'as usual'.

## 1754-1775

p 66 (1 June 1758): Ordered that the back burying ground be shut up till further order and that the Pest House ground be opened for burials and the ground levelled.

p 78 (30 November 1758): Agreed that a reward of £5 be given to any person or persons who shall at any time detect and apprehend any person stealing a Corps out of any of the Burial Grounds belonging to the church, to be paid upon conviction thereof by the churchwardens.

1808-1821

pp 188-91 (12 October 1810): report of a committee appointed on 30 May 1809 re the state of the churchyards and burial grounds belonging to the parish, and fees required for interment.

That the vaults beneath the church [are] large and commodious but dark, damp, neglected and highly offensive. Sufficient ventilation not having been secured and wooden coffins having been admitted.

That the whole of the ground surrounding the church is denominated the north and south churchyards which are also neglected; that there are upwards of 40 tombstones much out of repair, being decayed, broken and their owners unknown.

That the burial ground on the north side of the churchyard is also divided into two parts by a row of trees and also called north and south Burial Grounds, and of which the north part is higher than the south, and for interment wherein lower fees are required. Similar neglect displayed, and immediate improvements required.

That the ground commonly called the Pest House Ground is situate in Pest House Row [and] is a large plot of ground principally appropriated for the interment of paupers - but which by a change of name and a trifling expenditure may be rendered convenient and productive.

The north burial ground is nearly filled. May need to purchase additional churchyard at considerable and burdensome expense.

The Committee recommend that funerals of opulent inhabitants should be promoted in the vaults and churchyards; that the burial grounds should be made convenient for persons in middling circumstances, and that the Pest House Ground should be also so improved as to be acceptable for the interment of the poor inhabitants.

That for these purposes the Committee think that the fees for interment in the vaults and churchyards should not be enhanced, that fees for interment in burial grounds should be more equalised and rather increased, and that very moderate fees should be charged for interment in the Pest House Ground.

That for these purposes the Committee recommend that apertures should be made in the walls at the east and west ends of the church, of 3 feet in diameter that they [sic] may be ventilated 2 That the grave diggers be employed to collect all the remains of the dead and inter them in one hole and 3 That hereafter no corpse be permitted to be placed in the vaults except in leaden or metal coffins.

0200

p 195 Burial fees

Burial in vaults and churchyards, £2 10s  
South Burial Ground, 12s  
North Burial Ground, 9s  
Pest House 4s

For every vault to be purchased under the church to be enclosed at per square foot, 5s.

p 196 That corpses of all persons whose families have vaults or graves with flat or head or footstones, although they were non residents at the time of their death, shall be regarded as resident parishioners and pay only a single fee.

p 197: estimated costs:

Digging holes and for removing remains from the vaults, 5s 5d  
Apertures to the vaults in the church £100.

[Indexes of other Vestry Minutes volumes for 1775-1808, and for 1821-49 checked for VAULT or CRYPT entries. None of any significance found]

July 1849-October 1855

p 6, 24 July 1849: parochial interments: re north burial ground, including poor burial ground in Bath Street.

p 109 25 June 1850: Metropolitan Interments bill noted, re mortuary fees payable. Now before the Lords.

p 236 10 September 1851: repairs (unspecified)

pp 299-300 27 April 1852: repair needs itemised. Include 'limewhiting the walls leading to the vaults, 10s 6d'

p 411, 27 October 1853: Burial grounds Interments. Petition to Viscount Palmerston for an extension of time for closing burial grounds and vaults of this church turned down: burials (including those in the vaults) to be discontinued at the end of this year. Vestry inclined to remonstrate on grounds that Privy Council were 'violating the intention of the Legislature'. Much collecting of signatures (transcribed into the Minutes), but nothing came of it.

\* [subsequent volumes of Minutes not checked and, once burials had ceased, unlikely to contain much of interest except (at best) for occasional sealings and tidying up] \*

2) Photos; exterior, interior; churchyards, rectory. None of the crypt. L2.53

3) LCC: *Return of burial grounds in the county of London* (1895)

pp7-8 Whole ground amounts to 1¼ acres. 'Piece round the church is closed, and full of large altar tombs, ivy being planted most profusely.' 'The part on the north side was laid out as a public garden in 1878, and is maintained by the Vestry. It has been temporarily closed this year for new drainage and alterations.'

4) C R Simpson, *St Luke's church, Old Street, London EC1, 1733-1933: a short summary of its history* [1933]. Useless.

5) Oblong box: L2.53: ST LUKE'S CHURCH

Contents include:

Kerry Downes, 'A church with an obelisk steeple', *Country Life*, 8 September 1960. Doubts about stability of the church from the very start. Vestry minutes apparently available to KD.

*Report of Borough Engineer and Surveyor, 29 March 1976* concerning settlement of the foundations, which rest on timber piles decayed due to rapid loss of moisture caused by movement of ground water. The north-east corner has settled by 4 inches in relation to the rest. The foundations of the south wall, east wall and east end of the crypt have been underpinned. The only part of the foundations now requiring attention is part of the north wall and the east end of the crypt. Apart from the north wall and the north end of the east wall the external walls of the building are in good condition.

*Report of Parks and Recreation Manager, 29 March 1976*: details of churchyard layout, including trees.

*Report of Borough Engineer and Surveyor, 28 June 1976*: The Recreation Cttee on 12 January 1876 authorised the Borough Engineer to investigate the safety of St Luke's foundations at a total cost of £500. This involved shallow trial pits dug inside the crypt to probe the foundations. When men entered the crypt they discovered that about 25% of the area had been sealed off by bricking in the access vaults. The conditions they found after unsealing the vaults were rather unpleasant with skeletons exposed, and the contractor's men were uneasy about digging through the floor.

Text of *Pastoral Measure of 1983*, giving notice of intention to remove human remains and dispose of memorials. Relatives have until 11 September 1989 to give notice. Remains and tombstones, monuments and other memorials to be removed from part of the said church and churchyard, and reinterred in another part of the churchyard.

*Report of the Borough Planning and Transportation Committee, 16 November 1987* re the Pattenmakers' proposals. Notes that the churchyard to the north was now a separate public garden; and that to the south also a garden but smaller and not open to the public for many years. Nothing about the crypt.

*Report of Development Control Sub-Committee, 4 February 1991:* St Luke's church and churchyard in re Pattenmakers' Company's proposals (which included provisions for archaeological excavation for 9 months). Major snag identified was traffic control and access. But sees no chance of a better, or even an alternative, scheme. No reference to vaults.

6) Bound book: *Metropolitan Borough of Finsbury: St Luke's Burial Ground*

An alphabetical index of persons buried at the south burial ground: some 180 entries relating to 161 tombs, details of whose inscriptions (where still legible) are given in the following pages, pursuant to the Open Spaces Act 1906. Gummed onto the front endpaper is a notice by the Borough of Finsbury, dated 17 June 1937, of its intention to apply for a faculty for permission to remove and change position of tombstones or monuments in the burial ground adjoining St Luke's being at the front or south of the church abutting Old Street. Persons with families interred there are invited to communicate.

7) Bound book: *Minute Book of the St Luke's Church and Burial Grounds Improvement Committee, 1875-8*

Schemes of November 1875 for repairing fabric of the church, reseating the interior and laying out burial grounds attached.

14 March 1878: visit of Dr Tristram, Vicar-General of the bishop of London, to inspect the burial ground at the back of the church, including the alterations made (gravestones set back from the centre of the burial ground to the side at the northern end). His view was that all inscriptions on the stones should be preserved and not buried in soil, and that additional powers would be necessary for removing 'such stones as were not actually in the way of such paths as were shown in the plan'.

19 March 1878: Agreed that flagstones be laid down in the front churchyard and opposite the west entrance to complete the whole area between the church and the wall of the graveyard.

8) 23 February 1877: Tristram: response to a petition from St Luke's to underpin south and east walls etc., including reseating, removal of upper gallery and resealing of the ground floor.

9) *Letters from rector to Tristram in 1895:* 12 November, concerning a scheme to transfer the back burial ground to [? Borough of Finsbury] for them to use and keep in order and retain the front burial ground. Is a faculty necessary for this? The Vestry thinks that the rector can do it on his own authority, but he is concerned about an annual payment to him from the churchwardens of £200 as fees (as per Act of 6 George II, cap 21) for all burials and for making vaults and interments in the crypt of the church. This has not been paid for some years (though after burials ceased at the church it had at first been paid from other sources). But he doesn't want to risk prejudicing his successors' rights to the payment by transferring the freehold. Tristram's reply not recorded

Burial Fees from: *Joseph Turner, Burial Fees of the Principal Churches, Chapels and New Burial Grounds in London and its Environs... and all...Information for Undertakers c.1838.*

**The Minute Books, 1711-27 of the Commission for Building Fifty New Churches**

***Minutes of the Commissioners***

*5 Dec 1711*

Mr Willims offered a site for a church etc., called the Mermaid Brewhouse in White Cross Street in St Giles Cripplegate at £550.

***Minutes of the Building Committee***

*24 Sept 1712*

Skeat delivered Ironmongers' Companys' proposal for church near Old Street, Cripplegate.

Mr Wren and Mr Marlove desired to view sites belonging to....Ironmongers' Company in St Giles Cripplegate and report.

*30 Mar 1713*

Agree to Ironmongers' Company proposal of 23 March for site in St Giles Cripplegate, providing Company consent to build street leading thereto from Old Street before 25 March next. Otherwise, agree to proposal of 24 September last.

***Minutes of the Commissioners***

*10 Aug 1716*

Agreed to give Ironmongers' Company £900 for their site in St Giles Cripplegate parish.

*25 July 1717*

A debate arising upon the fifth article of the Ironmongers' Companys' proposals, resolved that no houses should be nearer than 25ft to churchyard wall, and no buildings nearer than ten feet.

*12 Sep 1717*

James to bring designs of a church for the Ironmongers Company site in St Giles Cripplegate parish by next meeting; masonry between the compartments of windows to be range work of rag stone; Surveyors (Hawksmoor and James) to call on masons employed in churches to give estimates for rag stone.

10 Oct 1717

CL200

James submitted design of church for Ironmongers Company site, St Giles Cripplegate.

The said plan approved; James to bring two estimates to next meeting: one built with ashlar, the other with rag stone.

28 Nov 1717

Notice to be given in Saturdays Gazette for bricklayers proposals for new church in Old Street, 'with the best hard burnt bricks, free from sammel or under burnt bricks'.

23 Jan 1717/18

Notice to be given in Gazette for receiving bricklayers and brickmakers proposals for Old Street church this day fortnight.

13 Feb 1717/18

Surveyors reported on brickmakers proposals; referred to next meeting. Wilson, as most reasonable of the bricklayers proposals, appointed for Old Street church.

20 Feb 1717/18

John and Thos. Waxham to make good, hard, well-burnt bricks for Old Street church.

27 Feb 1717/18

Notice to be given in Gazette for proposals for digging foundations of Old Street church by this day fortnight.

13 Mar 1717/18

Form of contract with workmen for Old Street church to be considered at next meeting

19 Feb 1718/19

Petition of James Wilson about one of the houses to be demolished on Ironmongers Company site to be complied with.

12 Mar 1718/19

On Dr Bennet's request, Surveyors to give orders for clearing ground in order to begin work on church in Old Street. James to prepare a plan and estimate for building in brick.

25 May 1720

OLR00

Surveyors to estimate charge of fencing site in Old Street; Skeat to consult Wilson about preventing soil being laid there in future.

Hawksmoor reported that the ground in Cripplegate (Old Street) purchased of Ironmongers Company is large enough for erecting a tabernacle without obstructing building a church on another part of it when Board is enabled to do so.

17 Apr 1721

Agent submitted proposals for parts of ground in Old Street from Jas Wilson, bricklayer and John Wilson.

Wilson to be allowed the ground upon which a church is intended to be built, to be cleared and given up at 3 months notice.

3 May 1721

John Wilson attending, the Board refused to let him the ground in Old Street upon which a church is intended to be built unless he consented not to raise it above present level, with which he would not comply.

20 Mar 1723/4

Solicitor to have fresh directions to prosecute any who lay dirt or rubbish on site purchased in Old Street.

15 May 1724

Bennet reported that, having acquainted vestry of St Giles Cripplegate that he had delivered to Commissioners the vestry's agreement to convey to them Bear and Ragged Staff Yard provided they would allow parishioners to bury in the ground in Old Street, and that Commissioners had answered that they were willing, as soon as conveyance was made to divide the parish and give parishioners of Old Street church district free leave to bury there, vestry unanimously acquiesced.

23 Jun 1727

A plan for a new church to be erected in parish of St Olave, Southwark was laid before Board, and another plan of a church to be built in Old Street in parish of St Giles Cripplegate; both approved.

Surveyors ordered to direct workmen to begin digging foundations without loss of time.

24 Jul 1727

OLR00

Goff's proposals for smith's work at Old Street church approved; Solicitor to prepare contract

Advertisement ordered for mason's proposals for Old Street church.

4 Aug 1727

Mason's proposals for Old Street church referred to Surveyors.

25 Aug 1727

Surveyors having examined mason's proposals for Old Street church, Thos Sheperd to be employed.

11 Sep 1727

Solicitor to prepare contract with Jas Wilson and Benj. Prosser, bricklayers for Old Street church.

22 Sep 1727

John Beven to be employed as watchman, Old Street church.

27 Oct 1727

Read petition from Wilson, now in prison, praying he may be permitted to go on with brickwork of Old Street church. Surveyors to learn what proposals he will offer about finding security for his performance.

10 Nov 1727

De la Motte, an assignee of estate of Jas Wilson, bricklayer, a bankrupt, declared on behalf of creditors that he had no objection to Commissioners discharging Wilson from his contract and agreeing with another.

Hawksmoor and James having some time ago complained to Wilson of his not setting about bricklayers work at Old Street church, and he promising to set about it and to bring good security to Board this day for performing the contract, or he would be content to waive it; and Wilson not having begun it, or brought any security, and being a bankrupt and prisoner in Ludgate for upwards of a year, Commissioners judged that he ought not to be employed at Old Street church.

Benj. Prosser and Wm. Cooper, bricklayers, proposing to do the work on the terms in Wilson's contract, proposal accepted; Solicitor to prepare contract.

## Appendix 2: Test Pit Report

00000

Robin Wroe-Brown, September 1996

An archaeological watching brief was undertaken on five test pits excavated against the exterior walls of St. Luke's Church, Old Street, Islington. The test pits were commissioned by Ove Arup in order to assess the composition and state of repair of the foundations to the church and the material in which they were constructed. The scope of the archaeological work involved observing the excavation of the test pits, and halting the work if articulated human remains or archaeological material predating the construction of the church were uncovered. The position of the test pits was decided by the Ove Arup representative, Thomas Philip, who also oversaw the work as it was carried out.

N.B. The numbering of the test pits in this document, TP1 - TP5, is purely based on the order in which they were opened and may not relate to the numbers used by the contractors.

### Methodology

The test pits were all excavated by machine, a Kubota KX151 360° tracked mechanical digger with a non-extendible arm, which achieved a maximum depth of approximately 3.7 m. Any further removal of material necessitated shoring the trench and excavating by hand. This work was undertaken by the contractors, J.N.K. Excavations. Where it was appropriate and safe for close examination, the pits were shored using two hydraulic trench sheets and access was provided by an extension ladder. This proved to be possible only in TP2, TP4 and TP5.

### RESULTS

#### Test Pit 1

2.5m x 2.2m x 3.15m deep. Top level = 20.44m OD.

TP1 was situated adjacent to the most serious cracking on the north wall, approximately 17m east of the NW corner of the church. It measured 2.5m E-W and a maximum of 2.2m N-S. The western half of the pit had been excavated previously in the 1970's (pers. comm. Thomas Philip) and the backfill was very loose and unstable. Thus the pit was extended eastwards into less disturbed ground. During the course of the excavation several disarticulated human bones were observed and the machine also uncovered at least three burials on the northern edge, one of which was that of a child. Under the circumstances it was decided to narrow the pit to 1.5m N-S in order to avoid further disturbance. The machine could not penetrate the ground deeper than 3.15m without destroying the graves to the north and as the pit was too dangerous to enter it was decided to record the exposed material from the top and abandon attempts to dig further.

The deepest material was a compact sandy silt layer which appeared to be later than the adjacent foundation. It was encountered at 2.6m but may have been higher on the extreme N side. Above this lay a loose pale grey sandy silt containing frequent mortar.

ALROO

The top 1.9m consisted of loose brick rubble and mortar in three distinct layers. A brick drain ran across the test pit E-W at a depth of 1.1m, truncated by the later excavation. The presence of a cut 1.8m deep was noted on the N side, possibly a grave, although there was no apparent evidence of bones or a coffin in the thin strip observed.

The foundation of the church itself was red brick, stepped out at intervals. The base of the foundation was not exposed in this test pit.

#### Test Pit 2

1.3m x 2.7m x 3.6m max. depth. Top level = 20.41m OD.

The test pit was positioned adjacent to the steps leading up to the vestry door against the N wall of the church, well within the area of subsidence. There were many fewer disarticulated human bones noted in TP2 and only one burial was seen, the feet of which were exposed in the W section. The material was more stable than that in TP1 and it was possible to shore and enter this test pit. Both the E and W sections were recorded.

A very similar sequence to that in TP1 was observed on the W side. The deepest layer was a moderately compact grey/brown sandy silt unearthed at 2.2m deep. Above this lay a deposit of silty mortar and brick rubble, with looser brick rubble and mortar above. The brick drain curved to the north following the line of the vestry wall. Beneath it, in a very obvious cut, was the burial mentioned above, the feet of which were disturbed but otherwise it was left untouched.

The same layers occurred in the E section, but they were truncated by the insertion of a red brick wall 0.5m below the ground surface and standing 1.5m high. It was 1m north of the church wall and extended beyond the N section of the test pit. It seems likely that it was the exterior of a burial vault.

The stepped brick foundations of the church continued to a depth of 3.45m and they were found to be constructed on a compact stone rubble layer, including occasional chalk. The stones within the layer were large, up to 0.45m across, and apparently spread in a fairly haphazard fashion.

#### Test Pit 3

1.3m x 2.4m x 2.8m deep. Top level = 20.58m OD.

It was decided to situate test pit 3 against the south wall of the church 3.4m from the east end. A 0.5m thick concrete slab had to be broken out before excavation could take place. No human bone, articulated or otherwise, was noted and the extremely loose nature of the material meant that shoring and entry to the pit was impossible. A modern drain, probably for rainwater drainage and still in use, precluded excavating to depth on the south side and the test pit had to be narrowed by 0.4m.

OLR00  
A moderately compact mid-dark grey sandy silt was observed at the base of the test pit, similar to layers recorded in other test pits. It was truncated at 2.4m deep by the construction of a red brick wall, possibly the south wall of a burial vault. At a much later date the material on both sides of the wall was removed, presumably in order to conduct remedial works either to the foundations of the church or the ground surface. This must have entailed the emptying of the vault down to its floor, the disturbed brick remains of which were visible in the eastern section. The area both sides of the vault wall was backfilled with loose mortar and brick rubble, including yellow stock bricks, and the vault was covered with a yellow brick arched capping sprung between the vault wall and the foundation of the church. The presence of yellow stock bricks dates this work to the 19th or 20th centuries.

#### Test Pit 4

1.35m x 2.05m x 3.9m max. depth. Top level = 20.57m OD.

Test pit 4 was located against the east wall of the church 0.45m from the SE corner. The machine driver experienced a certain amount of difficulty in manoeuvring in the space between the wall and the fence bordering Ironmonger Row but a satisfactory result was eventually achieved. The trench was adequately shored and entry into it was possible. Very few disarticulated human bones were found and there was no sign of burials.

The fill of this test pit was uniform moderately loose mid grey/brown sandy silt with very frequent brick and stone inclusions. The northern section contained the southern edge of a yellow brick wall, probably part of a lightwell into the crypt beneath the church, which showed signs of subsidence on its underside. The exposed foundations of the church itself were not stepped out in the same way as other observed parts and they had been substantially rebuilt and underpinned at a late date. The deepest 0.5m exposed included yellow stock bricks. The bottom of the foundation was not seen. Evidently this area had undergone remedial work at some stage and any burials or other archaeological material had been cleared.

#### Test Pit 5

1.35m x 1.8m x 3.7m deep. Top level = 20.45m OD.

The final test pit was sited on the north wall of the church 0.35m east of the tower steps. No burials were found, although a quantity of disarticulated human bone was discovered. The trench was successfully excavated to full depth and shored to allow access.

The deepest deposit proved to be a soft mid grey sandy silt with frequent pebble inclusions. It was exposed at a depth of 3.8m and covered by 0.1m of hard gravel, possibly forming a surface. Above this the sequence was similar to that in TP1 with loose grey/brown sandy silt underlying mortar and brick rubble. A brick drain ran diagonally across the trench from the SE corner to the NW. Its cut was 2m down from the surface at its deepest point.

As in TP2 the base of the brick foundations to the church was observed at 3.45m and the underlying rubble layer was again present. It contained mostly chalk at this end of the wall.

## CONCLUSIONS

It was not clear from the test pits whether the foundations to the church were constructed in a trench or whether the surrounding material was dumped later. The investigations did not reveal any archaeological deposits which were demonstrably earlier than the church, although the layers at the base of TP2 and TP5 may have been contemporary with its construction. This particularly applies to the hard gravel surface in TP5 which may have been employed as a construction surface for part of the foundations. The only physical evidence for earlier activity on the site is circumstantial, the very fact that the church has subsided so severely on the NE quarter. There is a reference in the GLSMR to a possible medieval manor house on the site and there are known to be quarries and fishponds dating from the medieval period in the vicinity. It is possible that the existence of a such a feature beneath the foundations has caused the problem.

It would seem that there are few inhumations in the immediate vicinity of the church. This may be due either to the disturbance by later remedial work on the foundations or to the possibility that few burials were placed adjacent to the walls. However, any excavation more than 1.5m-2m from the masonry would be likely to encounter burials, such as those in TP1 and TP2, and the graves are not particularly deep, those in TP1 being less than 0.8m down. The presence of external burial vaults, as in the cases of TP2 and TP3, is also probable.

The recording system used was taken from the Museum of London Archaeological Site Manual (Third edition 1994) and are held under the unique Museum of London site code SLU96.

## EXECUTIVE SUMMARY

Construction and refurbishment works are planned to take place at St Luke's Church, Old Street, London, in order to provide new rehearsal and educational facilities for the London Symphony Orchestra. These works will entail clearance of post-medieval interments from the crypt and part of the churchyard. Part of the church will be underpinned, the structure of the crypt will be consolidated and the vestry will be cleared.

Measures are required to mitigate the impact of the proposed works on the archaeological works. Post-medieval funerary deposits can yield a wide range of archaeological and historical information. Although as yet not fully understood, interrogation of the condition and potential of the resource at St Luke's suggests that it is likely to be incomplete and in poor condition. In particular the crypt is known to be highly disturbed as a result of many episodes of grave-robbing and vandalism. These conditions and the very poor structural condition of the crypt, which impose constraints regarding health and safety, mean that the potential of the resource is limited.

It is probable that archaeological resource available at St Luke's cannot yield a statistically valid sample required for many issues relating to general population studies and biological anthropology. It is possible, however, that the resource can help to understand a limited number of questions regarding those who were buried at St Luke's. The resource may be useful in two further ways. The material can further our understanding of the taphonomy of crypts and churchyards and it may contribute to the development of techniques for the scientific analysis of human remains from funerary deposits.

It appears that the potential of the resource does not merit full archaeological excavation. Rather, it is proposed to undertake an archaeological watching brief on the clearance of the human remains by a commercial undertaker, with specific objectives relating to the potential discussed above. Thus, the watching brief will be geared towards: the characterisation of the preservation conditions within the crypt and churchyard; the recording of inscriptions on the coffin plates; the recording of human remains with and without associated biographical details; the recovery of limited samples of human skeletal remains from those interments with biographical data; and the recording of the crypt structure.

Despite anecdotal evidence, the conditions within the crypt are not properly understood. It may be that the archaeological potential is lower or higher than is currently modelled. Consequently, the assumptions regarding preservation and potential will be reviewed at key stages in the project and the mitigation measures will be adjusted, in consultation with the client, English Heritage (the Greater London Archaeological Advisory Service), the Heritage Lottery Fund, Islington's Environmental Health Officer.

## 1. INTRODUCTION

### 1.1 Description of the project

1.1.1 St Luke's Church, Old Street (Figure 1, grid reference TQ 32320 82423), is an eighteenth century church. Today it is a disused, roofless structure. It is Grade 1 listed. The walls of the nave, tower (attributed to Hawksmoor) and vestry survive. Beneath the church there is a crypt, with a number of vaults or bays containing coffined human remains (Figure 2). The church lies within its churchyard, set back from the busy east-west running Old Street, within the London Borough of Islington. There are known to be both earthen and vaulted graves within the churchyard. The yard has been the subject of landscaping. No headstones survive *in situ* but a small number of chest tombs remain. The chest tombs, railings and gate are listed grade 2.

1.1.2 The St Luke's project involves the refurbishment of the church to provide rehearsal and educational facilities for the London Symphony Orchestra. Partial funding has been obtained from the Heritage Lottery Fund. The refurbishment work includes the underpinning of the external walls, the provision of a new roof, conservation of the structure and the clearance of the crypt and part of the churchyard to accommodate the construction of additional space at basement level.

1.1.3 The construction and refurbishment works will have an impact on the archaeological resource in the following ways:

- Human remains will be removed from the crypt and graveyard
- Construction work in the graveyard and crypt may disturb potential archaeological layers beneath the lowest burial levels
- The works will require disturbance to and the removal of some elements of the building structure, including the crypt.

1.1.4 This project design for the mitigation of the disturbance to the archaeological remains has been prepared by WS Atkins Heritage. It sets out the background, objectives and methods for archaeological mitigation. Once agreed with English Heritage, the archaeological work will be put out to tender to archaeological contractors. Contractors will be asked to provide in support of their tender, a detailed method statement, including recording methods, a health and safety risk assessment, methods of collection and storage of samples, an indication of resources and proposals for publication. The selected method statement will also be submitted for approval. Together, this project design and the detailed method statement, will form an archaeological written scheme of investigation (English Heritage, 1998a).

### 1.2 Key personnel

1.2.1 The following people are involved in the archaeological elements of the project:

Managing Consultants to the project	The Arts Business Contact: Philippa Bird
--	---

Archaeological Consultants	Janet Miller of WS Atkins Heritage with Dr Margaret Cox and Paul Kneller of Bournemouth University
Archaeological advisor to Islington Borough Council	Jez Reeve, Greater London Archaeological Advisory Service, English Heritage
Archaeological advisor to the Heritage Lottery Fund	Dr Anna Ritchie
Public Health Laboratory representative and Public Health Advisor to the project	Dr Susan Young FRCP Dip Bact
Agents for the London Diocesan Fund	Biscoe Craig Hall Contact: Bob Wilson
Architects and contract administrator	Levitt Bernstein Contact: Rob van Hove
Enabling works contractors and exhumation specialists	Necropolis

## 2. GENERAL BACKGROUND TO THIS PROJECT DESIGN

2.1.1 An archaeological desk-based assessment of the site was undertaken by the Museum of London Archaeology Service in 1996 (MoLAS 1996).

2.1.2 This was followed by an assessment of the archaeological potential of the site, particularly in relation to the study of post-medieval human remains, and the development of recommendations for archaeological mitigation (Cox M, 1997 and Cox M, 1999).

2.1.3 A conservation plan for the site and building recently has been prepared by Purcell, Miller and Tritton.

2.1.4 The mitigation proposals developed by Dr Cox have been accepted and approved by the Heritage Lottery Fund and the archaeological advisor to the London Borough of Islington. The aim of this project design is to develop the research objectives, details and arrangements of the mitigation works.

### 3. ETHICAL AND RELIGIOUS CONSIDERATIONS OF EXHUMATIONS AT ST LUKES

3.1.1 The exhumation of any buried remains at St. Luke's will have serious ethical and religious implications, which are of primary concern both to the local religious authority (The Diocese of London) and to the archaeologists.

3.1.2 The buried human remains in the graveyard were laid in consecrated ground as part of Christian tradition and ceremony. All those involved in the exhumation of these remains are charged with the responsibility of acting with reverent care and attention in all their associated works. The burials represent the remains of past parishioners of the church of St. Luke's and thus particular consideration should be afforded to the sensitivities of anyone with personal connections with St. Luke's in all excavation and reinterment works.

3.1.3 Particular policies for the exhumation and excavations at St. Luke's, based on ethical considerations are set out below. For the purposes of this project, a sealed coffin is defined as an unbroken lead coffin with the lid intact.

- *The treatment of sealed coffins (lead only):* based on knowledge of similar burial conditions at Christ Church Spitalfields, it is considered that very few coffins will still be sealed, and those which are, are likely to be lead coffins. All sealed lead coffins will remain sealed, will be sleeved on site and removed for reburial.

- *The treatment of open or badly damaged coffins (lead or wooden):* subject to medical opinion, archaeologists will inspect remains in those coffins which are already open, or have sustained significant damage due to the conditions of deposition or disturbance. This may include lead coffins which on first inspection remain intact but which rupture on removal. The contents of these coffins, i.e. the remains and any associated grave goods, will be recorded (see below) and removed for reburial, preserving the integrity between remains and grave goods.

### 4. SUMMARY OF THE ARCHAEOLOGICAL BACKGROUND

4.1.1 St Luke's was consecrated in 1733. The site lies on brickearth over Third Terrace gravels of the River Thames. The site also lies on the edge of what was Moorfields Marsh, which is known to have been land-filled in the early post-medieval period (MoLAS 1996). The building has been prone to subsidence and cracks are visible in the north and south walls.

4.1.2 Little is known about earlier activity on the site. It is possible that Old Street was a Roman Road, perhaps on the line of an earlier route which linked two important river crossings, at Old Ford and Putney (MoLAS 1996, 15). The site lay to the north of and formed part of the hinterland of the Roman city of Londinium and it is likely that the site was used for farming or horticulture. This appears to have continued into the Medieval period, when cottages or tenements may have been built on the site. It is also possible, however, that quarries and fishponds were located here. The site appears to have been on the extreme northern edge of the Moorfields Marsh, which in

the very early post-medieval period became a large landfill dump, becoming filled with nightsoil and demolition debris. It is unclear whether St Luke's lies on the higher ground on the extreme north-west limit of the Moorfields Marsh or whether in fact it is founded on the marshy ground (MoLAS 1996).

4.1.3 The desk-based assessment did not address the number of interments in the churchyard and crypt (MoLAS 1996). However, if St Luke's emulates those of similar dimensions and chronology in London, the interments may number tens of thousands (Cox, M 1997). The crypt was used for burial from around 1740 until interments ceased in 1853. Many of the interments were in wooden coffins. Although burials in the crypt were required to be encased in lead from 1810, it is likely that this rule was not always followed (Cox M, 1997, 3). The crypt had not been intended for burials and the structure was adapted for this purpose by the construction of vaults, probably in a number of phases, in an apparent *ad hoc* way

4.1.4 In 1964 coffins in the crypt were covered with a large amount of spoil and access to the crypt was bricked up. The imported spoil is believed to have contained human remains, having been brought from the churchyard north of Mitchell Street. Prior to the sealing of the crypt, coffins had been disturbed and damaged by a number of episodes of vandalism and robbing. Further episodes of vandalism occurred however, the last is believed to have taken place in 1994. Thus the deposits within the vaults have been heavily disturbed. Upper levels have been broken into and lower levels have been mined (Cox M, 1997).

## 4.2 Investigations within the crypt and churchyard

4.2.1 Although not for archaeological purposes, the crypt and churchyard have been investigated on a number of occasions. The commercial undertakers, Necropolis, undertook a investigation of the depth of deposits in 1964 as part of repair of the damage caused by vandalism, with the aim of re-arranging the coffins to prevent further damage (MoLAS, 1996). Some coffins were moved but later replaced in their original positions. It was found that up to three layers of coffins are buried beneath the earth floor. Access to the vaults was sealed following these investigations.

4.2.2 In 1976, at the behest of the Borough Engineer, shallow trial pits were dug inside the crypt to probe the foundations. It was observed that 25% of the area had been sealed off by bricking in the access vaults. After unsealing the vaults it was found that skeletons were exposed "and the contractor's men were uneasy about digging through the floor" (MoLAS 1996, 60).

4.2.3 In 1996, an archaeological watching brief was undertaken on 5 test pits excavated, for structural engineering purposes, against the exterior walls of the church, to a maximum depth of 3.9m. The foundations to the church were found to be red brick, stepped out at intervals. The east end of the church is particularly structurally unsound and evidence of earlier underpinning and repair was observed. No deposits pre-dating the church were identified, although one deposit may be associated with the construction of the building. Disarticulated human bones, burials and the walls of brick vaults were encountered in the trial pits, although there appear to have been few interments close to the church walls. It should be noted, however, that one burial observed in Test Pit 1 was only 0.8m below the present ground surface (MoLAS 1996, 68).

### 4.3 Current conditions

4.3.1 Despite these investigations, at present it is difficult to characterise the use, modifications and current condition of the crypt and its contents, except in very general terms. The crypt covers an area of 430m<sup>2</sup>. The floor level is said to be at 17.58m OD (MoLAS 1996). It appears that the crypt was effectively divided longitudinally into three by the foundations of the aisles. The area beneath the nave, appears to have been further divided, thus forming four east-west "vaults" beneath the main body of the church. All but the southernmost vault appears to contain burials beneath the earthen floor, probably extending across the entire floor area of these vaults and as mentioned above, apparently up to three coffins deep. At each end of the two central vaults and possibly at the east end of the northern vault, there are a number of individual brick vaults, built against the walls. Individual coffins are piled on the surface of the earthen floor. The structure of the crypt is known to be very unstable and in poor condition and with the extensive spoil and disturbance to the coffins and debris resulting from vandalism and grave-robbing, it can be assumed that conditions within the crypt are generally damp, dark, disorderly and poor, providing many difficulties not only for any archaeological investigations but also for the clearance of the crypt.

## 5. DETAILS OF THE CLEARANCE OF THE CRYPT AND PARTIAL CLEARANCE OF THE GRAVEYARD AND ENABLING WORKS

### 5.1 The exhumation and enabling works.

5.1.1 The exhumation of the crypt and part of the churchyard form part of the package of enabling works for the project. The specification and tender documents for the main package have been developed by Citex Bucknall Austin (Citex Bucknall Austin, 1999) but the specification for the exhumation has been prepared by Biscoe Craig Hall (Biscoe Craig Hall, 1999). Necropolis has been awarded the exhumation and enabling works contract and they have prepared a preliminary method statement.

5.1.2 In addition to the exhumation, the enabling works include:

- Erection of hoarding around the exhumation and construction area.
- Lifting, protection and removal to store of pavings
- Demolition of the vestry on the north side of the church
- Lowering of the ground levels within the crypt to formation levels, including the design and implementation of temporary support of the crypt structure
- Lowering of the ground levels in part of the churchyard to formation levels, including the design and implementation of the support of the church walls and adjoining churchyard area
- Design and implementation of underpinning of the north wall to the church.
- Provision of security and other on-site facilities - office accommodation, welfare, mess an washing and shower facilities
- Provision of secure accommodation of exhumed remains awaiting transportation
- Provision of mechanical plant and vehicles

## 5.2 Anticipated sequence of the enabling and exhumation works

The following are the principal activities of Necropolis which relate to archaeology. The sequence of these activities is subject to finalisation.

### 5.2.1 Phase 1

- Site establishment and erections of hoardings
- Dismantling and storage of railings and chest tombs from the churchyard
- Removal of a number of trees
- Demolition of the vestry
- Exhumation of the area adjacent to the north wall of the church
- Creation of a ramp on the north side of the church, leading from the crypt floor level up to the current surface of the churchyard.
- Creation of access through the north wall of the crypt, using an existing opening, now sealed

### 5.2.2 Phase 2

- Creation of a north-south access route through the crypt and working area, by the creation of openings through the vault walls and by the clearance of surface coffins along this route .
- Erection of shoring of the crypt structure
- Machine clearance (of the rubble and debris) of the central access zone to create a working area.
- Clearance of the main vaults and discrete vaults, of the surface coffins and human remains
- Exhumation of the churchyard area adjacent to the south wall of the church.

### 5.2.3 Phase 3

- Excavation of the crypt floor and trial pits below the floor
- Excavation of the crypt to formation level
- Excavation and clearance of spoil from the south churchyard
- Shoring of the church and the faces of the retained ground

### 5.2.4 Phase 4

- Exhumation of the north churchyard
- Underpinning of the north wall

### 5.2.5 Phase 5

- Excavation and clearance of spoil from the north churchyard
- Shoring to the church and faces of retained ground

## 6. POTENTIAL OF THE ARCHAEOLOGICAL RESOURCE

6.1.1 Following the completion of the desk-based assessment, recommendations for archaeological mitigation were prepared by Dr Margaret Cox of the School of Conservation Science, Bournemouth University, in consultation with Ms Jez Reeve of English Heritage (Cox, M 1997). That document explored the potential of the archaeological and human remains, including the crypt structure, using the criteria

recommended in *Planning Policy Guidance No 16, Archaeology and Planning* (DoE 1990):

- Completeness

The action of vandals, graverobbers and others within the crypt have affected the completeness and integrity of the assemblage of the human remains for the study of many of the issues which post-medieval crypts can often offer, such as population studies, is severely limited. The construction works in the churchyard will involve only partial clearance of the yard. Thus the full assemblage of human remains in the churchyard is not accessible to the project.

- Condition

The prevailing damp conditions means that a wide range of materials, including wood will have decayed. Prior to the introduction of the spoil in 1964, the coffins and human remains were exposed to the action of rodents, insects, bacteria and fungi. Moreover, that spoil apparently contained human remains from elsewhere. The vandalism, robbing and periodic re-ordering of the crypt will have disturbed and removed many elements of the archaeological resource and the placing of heavy lead lined coffins will have crushed any earlier unlined wooden burials beneath. The archaeological remains within the crypt are unlikely to survive in good condition and their archaeological potential is thus diminished.

Within the churchyard, the intercutting of the graves over the centuries means that it is likely that all but the latest graves may well be disturbed and incomplete. The cutting of drainage ditches, necessitated by the waterlogged conditions will not only have physically disturbed the burials but will also have brought any previously anaerobic conditions to an end. Landscaping activity, as well as tree roots will also have affected the condition and integrity of the deposits and remains.

- Rarity

This criteria is difficult to assess for St Lukes. Post-medieval funerary context have becoming a diminishing resource over the last twenty years but it is clear that other similar contexts do survive in London.

- Historical documentation

The MoLAS report has indicated that a wide range of historical documentation exists for this site which can be used to complement and augment the archaeological information.

- Group value

The archaeological resource of the crypt, the graveyard and crypt structure form part of the assemblage which is the St Lukes church complex. The site can also been studied within the context of the group of similar post-medieval churches and burials grounds within London. In principle these all add to the value of the resource which can be studied at St Lukes. However it might be argued that this value is undermined

by the incomplete nature and poor condition of the archaeological resource which will be affected by the development.

- The crypt structure

Despite the poor structural condition, examination and recording of the crypt and the vaults within it can shed light on the original structure and modifications to it. This can complement the archaeological information provided by the funerary remains and the historical documentation. The poor condition of the structure, however imposes health and safety constraints on all archaeological investigations within the crypt.

## 6.2 Constraints on archaeological investigations

### 6.2.1 Health and Safety

- The poor structural stability of the crypt means that health and safety issues have played a major role in the enabling contractor's development of the methodology of the crypt clearance and these considerations remain paramount for the archaeological work. Access and freedom of movement will be limited owing to the restrictions of space. Moreover, the disorderly conditions within the crypt, together with methods of crypt clearance mean that the archaeological resource will only become visible and available as the clearance progresses, rather than at the outset of the project. While this can pose difficulties for archaeological investigation it can be mitigated by the setting of clear objectives for the investigations.
- The clearance of human remains can pose risks both for public health as well as personal health and safety, in particular the infectious hazards associated with crypt conditions. The greatest concern for these is the Smallpox virus but which survives only on soft tissue (Young SGH, 1998). This can be dealt with by the adoption of appropriate personal protection equipment. However, in the opinion of Dr Susan Young, sealed coffins should not be deliberately opened during the clearance of the human remains.

### 6.2.2 The Church's wishes

- The London Diocesan Fund holds the freehold for the St Luke's church and surrounding burial ground. As the church is now redundant, the exhumations will not require a Faculty. Rather, section 65 of the Pastoral Measure applies. For reasons of decency and dignity, the Church Diocesan Fund has stipulated that sealed coffins should not be opened and that such coffins should be sleeved on site and removed for reburial.

### 6.2.3 Home Office directions

- Home Office directions are required for the removal of buried human remains. A Home Office order has been granted for the exhumations at the St Luke's. The current Home Office order relating to the exhumation works (dated 21

January 1999) stipulates that the removal shall be subject to agreement with the Chief Environmental Scientist for the London Borough of Islington.

## **7. RESEARCH AGENDA AND OBJECTIVES**

### **7.1 General and regional research objectives**

7.1.1 A number of recent investigations of post-medieval funerary deposits have demonstrated the wealth of information that can be obtained and the research questions that can be addressed of the material from these contexts (Reeve J and Adams M, 1993). Excavations in Christ Church, Spitalfields in London demonstrated that a wide range of information, ranging from the architecture, use and organisation of the crypt, the differential treatment of the coffins and interments, the decoration of coffins, the characteristics of disease, diet and other elements of the biological anthropology of the local population. Following these and other similar projects, Reeve has set out the range of potential research issues for archaeological investigations at such sites (Reeve J, 1998). To maximise the potential of the St Luke's material in relation to relevant research objectives, consideration needs to be taken of the survival and condition of the remains.

### **7.2 A working model of the potential of the archaeological resource at St Luke's**

7.2.1 Constraints on physical access prohibited detailed archaeological evaluation investigations, but through observations made during watching briefs of structural testpits and other expert commentary it is possible to model the current state of the archaeological resource with some confidence.

7.2.2 In addition to the disturbance caused by vandals and graverobbers, many of the coffins, including those which are lead lined, are likely to be crushed, broken or decayed to some extent, particularly where coffins have been piled on one another. In the churchyard, it is likely that all but the latest coffins have been disturbed and damaged by intercutting. In both contexts it is likely that many of the interments are now lacking some of the skeletal elements. It is possible however, that some coffins survive intact and some may even remain sealed. Any coffins which have been well-built with double or triple shells or lead lining provide the ideal anaerobic conditions for the preservation of soft tissue, even to the extent of full skin preservation. It is considered unlikely that in the conditions present in the crypt at St. Luke's, soft tissue will survive. Despite the higher likelihood of such conditions obtaining in crypts than in an open cemetery, however, Dr Susan Young has demonstrated that the survival of soft tissue is variable and is by no means restricted to these contexts or indeed to sealed coffins (Young SEJ, 1998).

7.2.3 A further issue which affects the condition and potential of the resource is the process of disinterment. The probable poor condition of the coffins and the heaviness of those which are lead-lined, mean that many which are currently intact, may break during lifting.

7.2.4 For the purposes of this project design, our general assumption, or model, is that very few of the coffins remain sealed but despite the aforementioned disturbance, a significant proportion of the interments will survive largely intact but without soft tissue, or indeed other organic remains such as textiles. A further assumption is that for a significant proportion of interments, biographical data, in the form of coffin plates, will survive. Those which have surviving coffin plates with biographical details might be regarded as having the highest potential: they are named, aged and sexed individuals, with available samples generally uncontaminated by intrusive remains. (Human remains are known to have been present in imported spoil brought from the churchyard north of Mitchell Street and deposited over the burials in the crypt.) These burials provide a valuable source for testing new scientific techniques: osteoarchaeologists need a sample of known identity to assess any new method of age at death estimation or sex determination (Scheuer in Cox 1998). In order to ensure that this potential is properly realised, priority will be given to the identification of these contexts and extraction of samples from them, prior to or during lifting.

7.2.5 It is proposed to build in review stages in the programme of the archaeological watching brief to reconfirm or refine the mitigation strategy as necessary, dependent on the state of preservation of the remains.

### **7.3 A research agenda for this scheme**

7.3.1 The deposits at Spitalfields, London demonstrated a variety of levels of preservation, with some burials having lain undisturbed since the crypt was sealed in 1857. This state of preservation is unlikely to obtain for any of the St Luke's burials within the crypt. The probable poor completeness and condition of archaeological resource of the crypt and churchyard may mean that this material does not have the potential to repay large-scale human population studies. However it may be that the resource does have the potential to address a limited number of research objectives which can be divided into the following topics:

1. Understanding how the crypt and graveyard have developed through time through discussion of the stratigraphy and formation processes on the site
2. Furthering our understanding and techniques of the investigation of post-medieval funerary contexts—their taphonomy and preservation conditions. Also fulfilling the potential to develop methods of analysis of funerary deposits themselves through the analysis of samples of remains with associated biographical details.
3. Development of our knowledge of funerary rites and treatment of the dead
4. The study of those who were buried at St Lukes – number of burials, the individuals interred, making use of headstones and coffin plates and recording osteoarchaeological information for those with or without biographical information.
5. Understanding of funerary material culture, including the use of coffins and coffin furniture
6. Analysis of the construction, use and modification of the crypt structure, and the tombs within it, and an understanding of the original appearance and development of the church and graveyard.

7. The understanding of activity on the site prior to the founding of St Luke's.

## 8. PROPOSALS FOR MITIGATION OF THE IMPACT OF THE SCHEME

### 8.1 Mitigation proposals

#### 8.1.1 It is proposed to undertake the following:

- Archaeological watching brief on the clearance of the crypt and churchyard by commercial undertakers, in order to record the number of interments, and biographical data on coffin plates. Thus the clearance would be undertaken jointly between the archaeological contractor and Necropolis.
- Recording of inscriptions on coffin plates, the creation of a database of the inscriptions and assessment and analysis of the data as a contribution to the historical record of the population who buried their dead at St Luke's.
- Archaeological recording of the graveyard landscape, to identify, if possible, the appearance of the original graveyard landscape, to recover and analyse the soil around interments. to record the number of interments
- Archaeological recording during disturbance to the structure of the church building, including the crypt.
- Investigation and recording of any archaeological remains beneath the lowest burial levels in those areas of the graveyard to be affected by the construction works (the potential for these remains is believed to be low), to identify and record evidence for the Moorfields Marsh and the landuse prior to the founding of the church.
- The collection of small samples of human bone for analysis to further the development of scientific analysis of skeletal remains. Only those remains with accompanying biographical and age details are useful for this analysis. Canine teeth and metatarsals will be extracted from each named and aged skeleton, during the clearance of the crypt and churchyard. Recent work indicates the effectiveness of scientific methods for the study of human skeletal remains in funerary contexts where issues such as diet and disease have been addressed (Bell LS and Lee-Thorp JA, 1998). In particular DNA work is important for the analysis of genetic relatedness, identification of sex and the DNA of the bacterium responsible for infectious disease, e.g. TB. Dental ageing methods are also being developed, specifically microscopic dental ageing methods (apical or root dentine transparency and cemental annulation) and biochemical methods (amino acid racimisation). Unfortunately, it is unlikely that a statistically valid sample, which would contribute to general population studies, can be recovered from the available resource at St Luke's. However the resource can help to not only develop these scientific techniques but also develop our understanding of diagenesis and the processes of decay. Such analysis requires the invasive sampling of skeletal remains, albeit very small samples (Bell LS and Lee-Thorp JA, 1998). Therefore, as there is no intention within this project to analyse, still

less curate, the human remains at a macroscopic level, which may precluded invasive sampling, it may be argued that the material at St Luke's is particularly suitable for microscopic analysis.

- The recording of the design motifs on coffin furniture. At Christ Church, Spitalfields, 273 design motifs were identified on the coffin furniture (Reeve and Adams 1993). It would be useful to analyse the coffin furniture at St Luke's, in the light of this assemblage by cross referencing the St. Luke's material with the information from Spitalfields. .
- Documentary research to enhance and augment the information recovered during the watching brief. This will be undertaken prior to the works on site in order to inform the recording methods.

## **8.2 Research objectives and methods**

8.2.1 Table 1 sets out the research objectives of the proposed mitigation measures. It aims to demonstrate the relationship between the research objectives, the potential of the resource and the methods and techniques to be adopted at St Lukes.

Table 1 The research objectives, potential of the resource and methods for archaeological investigation at St Luke's.

<i>What do we want to know?</i>		<i>Potential of St Luke's resource to meet the objectives</i>	<i>How do we realise the potential?</i>		
<i>Topics (No. in Research Agenda)</i>	<i>Questions/objectives</i>		<i>In the field</i>	<i>Documentary research</i>	<i>Post-excavation assessment/analysis</i>
<b>Preservation and taphonomy</b>  (Topics 1/2/6)	What are the preservation environments at St Lukes?	The preservation conditions, particularly within the crypt, are known to be very poor. It is not known how far this is typical of these contexts but this is a good opportunity to record these conditions and would be useful for future projects.	Observe and characterise environments during WB.  Characterise the formation processes in each of the three areas of exhumation.	Seek records relating to the organisation of interments of the crypt and modifications to the graveyard landscape, in parish and church records.	Establish outline narrative of past activities which will have disturbed the archaeological deposits and the formation process.
	What materials/elements of the resource survive in the St Lukes contexts	As above.	Observe the nature of survival of a wide range of materials and objects. Take appropriate samples of materials. Sealed coffins will not be opened.		If appropriate, analyse the taphonomic processes of the preservation and decay of a range of materials.
	How has the landscaping, in particular the planting of trees, affected the preservation of the	The churchyard offers a good opportunity to record these conditions, and would be useful for future projects	Record these conditions, particularly root disturbance, during the WB		

	interments within the churchyard.				
<b>General population studies</b> <b>(Topic 4)</b>	How many people were interred at St Lukes?	The resource is known to be highly disturbed and incomplete but approximate numbers should be recoverable.	Recover minimum numbers of interred individuals during WB in both crypt and churchyard	Compare these figures with the burial register	
	Who was buried at St Lukes?	Assume coffin plates survive in many cases	Record biographical data during WB in both crypt and churchyard	Compare with burial register	Create database of inscriptions
<b>The funerary landscape</b> <b>(Topic 6)</b>	What was the original structure of the crypt and how was it modified	<p>The crypt appears to have been modified and added to. This will be useful not only for the understanding of this funerary landscape but also as reference for other projects</p> <p>The constraints of the current structural instability and H&amp;S considerations may mean full recording of the structure is not possible.</p>	<p>Investigate and record (written, drawn and photographs) the original structure and evidence for modifications during the WB. Particular questions should be: what is the phasing of the walls which divide the crypt into 4 vaults? What is the character of these later additions? What is the character of the discrete vaults and what was the phase of construction of them? Did any parts of the vault receive decorative treatment?</p> <p>The fabric will be</p>	Investigate documentary evidence and plans for the construction and modification of the crypt	<p>If possible reconstruct the original and changing appearance of the crypt. Compare this with contemporary plans or accounts and consider the evidence provided by coffin plates.</p> <p>Discuss how this reflects attitudes such as to the dead and their disposal, social status etc. and the management of the crypt space</p>

**The site prior  
the founding  
of St Luke's  
(Topic 7)**

Was the church founded on the Moorfields Marsh Landfill? If so, what is the general character and composition of this deposit?

What activity was there on the site, prior to the landfill.

The interments are believed to be highly disturbed and incomplete. Many coffin plates may survive, but it is likely that coffins have moved from their original positions.

The grave cuts should be visible beneath landscaping deposits

It is not clear if this deposit extends onto this site. Limited trial pit investigation suggests not

It is not clear if evidence of earlier activity remains on the site, nor is it clear that the

characterised but no samples of building material or mortar will be taken

Record dates of death and location of coffin during WB.

WB on stripping (under archl supervision) of turf and topsoil (by machine by enabling works contractors). Hand archaeological excavation of archaeological layers until grave cuts reached. Record plan of grave cuts.

Record and sample deposit during WB

Observe for any such remains during the WB. If remains do

Incorporate these discussions with above.

Determine dates of and nature of landscaping from church, parish or council records.

Investigate existence of pictures, engravings or photographs of churchyard, prior to landscaping.

0100

**The development of scientific techniques for the analysis of funerary deposits**

**(Topic 2)**

How well does DNA survive in such contexts?

How can we use DNA to refine our understanding of such issues as genetic relatedness, identification of sex, the identification of disease?

development will impact on any such remains.

DNA does not survive well in bone from sealed lead coffins in which the body liquor is trapped (Harding V, in Cox ed. 1998 p.212)

The model predicts that in both the churchyard and the crypt, most coffins will be decayed or damaged and few will survive with their seals intact. Of those which survive sealed or intact, many will be broken during disinterment.

It is assumed that a significant number of interments can be related to a surviving coffin plate. However the disturbed nature of the material and the conditions and method of working may limit the potential of recovering uncontaminated remains

The working assumptions are that sufficient appropriate samples of human remains will be available to meet the objectives within this topic. These objectives also relate to the topic of preservation and taphonomy.

exist and will be impacted develop appropriate mitigation strategy

Evaluate model regarding potential (see Section 7.2) early in the WB in each of the three areas.

If model is incorrect re-assess the archaeological potential and mitigation strategy with regard to this topic.

If model is correct, collect samples of human bones from non-sealed interments with biographical details: 4 (undamaged if possible) metacarpals or metatarsals, canine teeth, both lower if possible, upper if not, and 2 molars without carious lesions)

Assess survival of DNA

Assess potential alongside database of biographical details and against original objective

If potential confirmed, analyse as appropriate.

	How can the analysis of dental remains contribute to the development of techniques for microscopic dental ageing methods and biochemical methods.	The above assumptions regarding the potential apply.	Evaluate assumptions as above.  If assumptions correct, collect dental samples from non-sealed interments with biographical details.	Assess potential alongside database of biographical details and against original objective  If potential confirmed, analyse as appropriate.
<b>The nature of funerary material culture</b>  (Topic 5/3)	What was the nature of the coffin decoration and what does this tell us about treatment of the dead and the undertaking industry?	It is unclear how many coffin plates survive. Given the nature of the re-interment, the ethical considerations, preclude removal of plates, coffin furniture and grave goods. A record of the details of these, would, however, add to the general reference collection of funerary furniture for London in this period.	Written, drawn and photographic records will be made on site.	Assess the potential against the taxonomy for coffin plate design in London.  If potential confirmed, analyse as appropriate.

## 9. GENERAL METHODS

### 9.1 The archaeological contractor

9.1.1 A professional archaeological contracting organisation will be appointed to undertake the watching brief. The team will include personnel experienced in osteoarchaeology, post-medieval funerary deposits and building recording. All members of the site team will have been inoculated against smallpox. It is envisaged that teams of at least two archaeologists will be deployed for each of the three areas to be subject to the watching brief, i.e. the parts of the churchyards to the north and south of the church and the crypt structure. Additional archaeologists will be included in the team as the pace of clearance or potential of the archaeological resource dictate.

### 9.2 Project review during fieldwork.

9.2.1 The realisation of the research objectives developed in this project design depends on the correctness of the assumptions relating to the presence and condition of the archaeological remains outlined above. It will be necessary to continue to interrogate the potential of the material at St Luke's, throughout the fieldwork and into post-excavation assessment, if the proper potential is realised or the collection or analysis of redundant material is to be avoided. If the potential of remains prove to be higher or lower than our assumptions, the mitigation proposals will need to be revised. If there are fewer bodies which can be related to coffin plates than has been assumed, a number of the research objectives, particularly those which relate to scientific analysis, may not be realisable. Conversely, if a large number of sealed coffins survive, it may become apparent that there is greater archaeological potential than has been anticipated, which may need appropriate refinement of the mitigation measures.

9.2.2 It is proposed to review the nature of the archaeological resource in relation to the potential and the research agenda for the project, at a number of key points:

- On completion of the clearance of human remains within the area of the churchyard adjacent to the north wall of the church. This will enable a prediction of the likely condition of the interments to the south of the church.
- On completion of the clearance of the access through the crypt. It is hoped this will enable a brief evaluation of the condition and survival within the main vaults.
- On completion of the clearance of the coffins from the surface of the crypt floor and initial evaluation of the extent and survival of interments beneath the crypt floor

9.2.3 These reviews will result in brief project progress reports, which will be circulated to the client, the Heritage Lottery Fund and the archaeological advisor to Islington Borough Council. Any proposed modifications to the mitigation strategy will be discussed and agreed with these parties. These reviews will be undertaken in addition to the post-excavation assessment of the recovered archaeological material.

### 9.3 Standards and guidance

9.3.1 The archaeological fieldwork will be undertaken in accordance with the Archaeological Guidance Paper *Standards and practices in archaeological fieldwork in London* (English Heritage, 1998b) and the Institute of Field Archaeologists guidance for archaeological building recording (IFA 1996). The general recommended approach, particularly with regard to the collection of scientific samples and Health and Safety, set out in Cox M and Kneller P (Cox M and Kneller P, in press) will also be followed.

### 9.4 The recovery of samples of skeletal material

9.4.1 While it is desirable to recover as large a sample as possible for scientific research, for reasons of health and safety and to respect the London Diocesan Fund's wishes regarding decency, it is not proposed to open sealed coffins in order to extract samples. For the purposes of this proposal, sealed coffins are defined as an unbroken lead coffin with the lid intact. Visual inspection will determine whether or not the coffin can be regarded as sealed, and the recovery of samples where appropriate, will be undertaken prior to the lifting of the coffin. Samples will be taken as detailed in Table 1.

### 9.5 Working with the commercial undertakers

9.5.1 The enabling works contractors have been asked to price for the removal of approximately 900 interments. The specification for the exhumation work stipulates that the enabling works contractor must "provide all necessary access arrangements and other facilities necessary for the collection and recording of archaeological data throughout the job and shall arrange his works so as to enable the archaeologists to record their observation without causing delay to the works programme" (Biscoe, Craig, Hall 1999, 4.15). A full-time archaeological presence will be maintained throughout the programme of excavations and clearance of human remains so that all human and archaeological remain can be investigated, recorded and recovered as appropriate as soon as it is exposed.

### 9.6 Enabling works contractors' methods of removal and disposal of coffins and human remains

9.6.1 Following appropriate archaeological recording and the recovery of samples, the enabling contractor will adopt the following procedures for the clearance and disposal of the human remains. The details have been taken from the Exhumation Specification (Biscoe, Craig, Hall, 1999, 4.1.6). The Method Statement as prepared by the enabling contractor is attached as an Appendix to this document. It is understood that the requirements of the archaeology will take precedence over the commercial exhumation contractor's work.

- The exhumation contractor will be responsible for keeping the excavations dry by creating sumps, cutting drains and providing maintenance pumps as well as for supporting the crypt structure and temporary shoring of the excavations within the graveyard.

- The coffins will be cleared by hand, using mechanical lifting gear where possible and in any case, with the adequate amount of personnel. Once the coffins have been cleared, the spoil and loose remains will be cleared by a small mechanical excavator. The human remains within this loose material will be extracted, placed in burial sacks accompanied by a grid plan location and where possible biographical details, and re-interred.
- Where possible, sealed coffins, both in the crypt and churchyard will be removed whole, avoiding breaking the seal. Such coffins will be sleeved on site and placed in transportation cases. Other human remains will be placed in burial sacks, accompanied, where possible, by biographical details, and placed in transportation cases.
- After removal of the coffins from the floor of the crypt, the floor will be removed (under archaeological supervision) and the coffins and/or human remains removed by hand. Within the churchyard, the topsoil will be cleared under the watching brief of both archaeologists and an experienced exhumation operative and the coffins and/or human remains removed by hand. In both cases, particular care will be taken with regard to brick vaults and shallow graves. The excavations will be made safe for the inspection and recording of remains prior to their removal. Where safe conditions cannot be achieved, the excavations will continue with the use of a mechanical excavator. In such cases, each bucket load will be carefully sifted at ground level.
- The transportation cases will be transferred to East London Cemetery for re-interment.
- In both the crypt and churchyard, excavations will continue until formation level is reached or until the lowest burials have been removed, whichever is the deeper.

## 9.7 Health and safety

9.7.1 Health and safety considerations will be paramount. Particular risks at St Lukes relate to the transmission of disease and hazardous microbes to both the workers on site and to the public at large, and to the structural instability of the crypt. The archaeological contractor's work will fall within Necropolis' health and safety regime. The archaeological contractor and consultants will adopt appropriate personal protection equipment and will follow the recommendations set out in Cox M and Knellar P, in press.

## 9.8 Monitoring of Archaeological works

9.9.1 All works will be monitored and approved by English Heritage

## **9.9 Post-excavation analysis and publication**

9.9.1 The analysis of the archaeological results on all but the scientific analysis of skeletal remains will be undertaken by the archaeological contractor. However, it is proposed that that an appropriate academic institution, probably Bournemouth University, will undertake the assessment, analysis and publication of the scientific samples. This may be resourced by the creation of a post-doctoral studentship. It is hoped that the two programmes of assessment and analysis will be undertaken in tandem. Ways in which the results of the separate analyses can be synthesised, particularly regarding the common research topics such as taphonomy and preservation conditions, will be explored at the post-excavation stage.

9.9.2 Proposals for publication and archiving will be included in the project scheme of investigation produced by the archaeological contractor.

Table 1

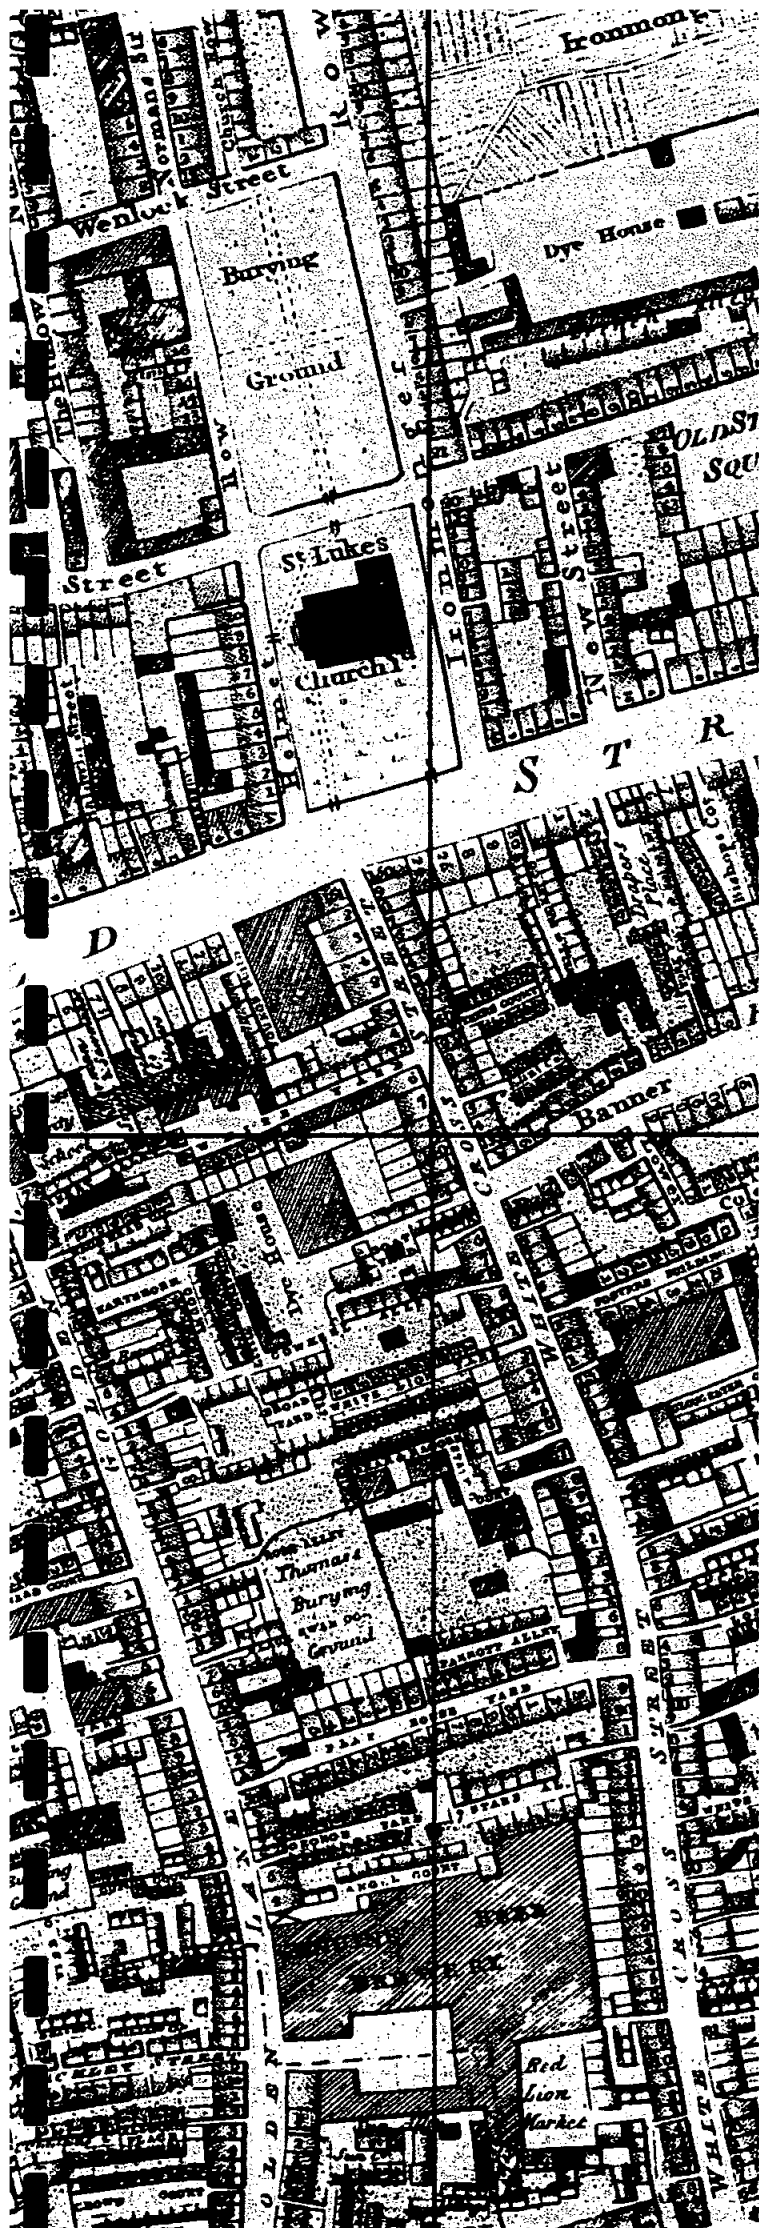

The research objectives, potential of the resource and methods for archaeological investigation at St Luke's.

Topics (No. in Research Agenda)	What do we want to know?	Potential of St Luke's resource to meet the objectives	How do we realise the potential?			Results of first project review	Preliminary results of post-excavation assessment
	Questions/objectives		In the field	Documentary research	Post-excavation assessment/analysis		
Preservation and taphonomy (Topics 1/2/6)	What are the preservation environments at St Luke's?	The preservation conditions, particularly within the crypt are known to be very poor. it is not known how far this is typical of these contexts but this is a good opportunity to record these conditions and would be useful for future projects.	Observe and characterise environments during WB	Seek records relating to the organisation of interments of the crypt and modifications to the graveyard landscape, in parish and church records	Establish outline narrative of past activities which will have disturbed the archaeological deposits and the formation process.	Preservation conditions in the churchyard and crypt are better than anticipated. Landscaping etc does not appear to have caused much disturbance to archaeological deposits.	Preservation conditions in the churchyard and crypt are better than anticipated. Landscaping etc does not appear to have caused much disturbance to archaeological deposits.
	What materials/elements of the resource survive in the St Luke's contexts?	As above.	Observe the nature of survival of a wide range of materials and objects. Take appropriate samples of materials. Sealed coffins will not be opened	Characterise the formation processes in each of the three areas of exhumation.	If appropriate, analyse the taphonomic processes of the preservation and decay of a range of materials.	Skeletal preservation is good on the whole. Preservation of coffin furniture is fair, better in vaults and in crypt. A number of types which do not appear in the Christ Church, Spitalfields corpus have been identified.	A total of seven samples have been retained for pedological analysis. Skeletal preservation is good on the whole. Preservation of coffin furniture is fair, better in vaults and in crypt.
	How has the landscaping, in particular the planting of trees, affected the preservation of the interments within the churchyard?	The churchyard offers a good opportunity to record these conditions, and would be useful for future projects.	Record these conditions, particularly root disturbance, during the WB				A number of types which do not appear in the Christ Church, Spitalfields corpus have been identified. It is recommended that these be fully catalogued and illustrated. Landscaping and tree planting does not appear to have affected the preservation of interments within the churchyard.
General population studies (Topic 4)	How many people were interred at St Luke's	The resource is known to be highly disturbed and incomplete but approximate numbers should be recoverable.	Recover minimum numbers of interred individuals during WB in both crypt and churchyard	Compare these figures with the burials register		A total of 750-1000 burials are now anticipated. Only limited disturbance has occurred. It is proposed that the entire skeletal assemblage should be subjected to high resolution recording. The scope of the documentary research should also be increased to include baptism and marriage registers and all other sources likely to contribute to the social reconstruction.	A total of 1016 burials were recorded and exhumed. The skeletal remains of a further 36 individuals were identified during osteological analysis.
	Who was buried at St Luke's?	Assume coffin plates survive in many cases.	Record biographical data during WB in both crypt and churchyard	Compare with burial register	Create database of inscriptions	Named individuals and family groups are present at St Luke's.	A total of 164 named individuals were subjected to high-resolution recording.  It is proposed that the scope of the documentary research be extended to include all available sources for the named individuals.  Stacks of burials have been identified within individual grave cuts. These may represent family groups. Database of inscriptions has been completed.  OAU has obtained microfilm copies of all burial registers.
The funerary landscape (Topic 6)	What was the original structure of the crypt and how was it modified	The crypt appears to have been modified and added to. This will be useful not only for the understanding of the funerary landscape but also as reference for other projects  The constraints of the current structural instability and H&S	Investigate and record (drawn and written and photographs) the original structure and evince for modifications during the WB. Particular questions should be:	Investigate documentary evidence and plans for the construction and modification of the crypt	If possible reconstruct the original and changing appearance of the crypt. Compare this with contemporary plans or accounts and consider the evidence provided by coffin plates.  Discuss how this reflects attitudes such as to the dead and their	Some burials in the crypt are located at a level below the base of the walls of the structure. There is now a suggestion that the roof of the structure be removed.	All burials were removed from the crypt using appropriate health and safety measures. The roof of the crypt was not removed.

	considerations may mean full recording of the structure is not possible.	what is the phasing of walls which divide the crypt into 4 bays? What is the character of these later additions? What is the character of the discrete vaults and what was the phase of construction of them? Did any parts of the vault receive decorative treatment?	disposal, social status etc. and the management of the crypt space.		
How was the crypt used through time? Is it possible to reconstruct the appearance of the crypt at the final interment? What did the churchyard look like before the first phase of landscaping?	The interments are believed to highly disturbed and incomplete. Many coffin plates may survive, but it is likely that coffins have been moved from their original positions. The grave cuts should be visible beneath landscaping deposits.	The fabric will be characterised but no samples of building material or mortar will be taken. Record dates of death and location of coffin during WB.	Incorporate these discussions with above.	Interments are not highly disturbed. Many coffins are likely to be in their original positions.	
		WB on stripping (under arch. Supervision) of turf and topsoil (by machine by enabling works contractors). Hand excavation of archaeological layers until grave cuts reached. Record plan of grave cuts.	Determine dates of and nature of landscaping from church, parish or council records. Investigate existence of pictures, engravings or photographs of churchyard, prior to landscaping.		
<b>The site prior to the founding of St Luke's (Topic 7)</b>	Was the church founded on the Moorfields Marsh Landfill? If so, what is the general character and composition of this deposit?	It is not clear if this deposit extends onto this site. Limited trial pit investigation suggests not	Record and sample deposit during WB	The ground appears to be very well drained. The church does not appear to have been founded on the Moorfields Marsh Landfill. No pre-church activity has been identified to date.	The ground appears to be very well drained. The church does not appear to have been founded on the Moorfields Marsh Landfill. No pre-church activity has been identified.
	What activity was there on the site, prior to the landfill?	It is not clear if evidence of earlier activity remains on the site, nor is it clear that the development will impact on any such remains.	Observe for any such remains during the WB. If remains do exist and will be impacted develop appropriate mitigation strategy		Possible construction layers and dump layers relating to the construction of the church have been identified and sampled.
<b>The development of scientific techniques for the analysis of funerary deposits (Topic 2)</b>	How well does DNA survive in such contexts?  How can we use DNA to refine our understanding of such issues as genetic relatedness, identification of sex, the identification of disease?	DNA does not survive well in bone from sealed lead coffins in which the body liquor is trapped.  The model predicts that in both the churchyard and the crypt, most coffins will be decayed or damaged and few will survive with their seals intact. Of those which survive sealed or intact, many will be broken during	Evaluate model regarding potential early in the WB in each of the three areas  If model is incorrect re-assess the archaeological potential and mitigation strategy with regard to this	Assess survival of DNA.  Assess potential alongside database of biographical details and against original objective.  If potential confirmed, analyse as appropriate.	Sample size is quite small. However, there is still potential for developing and refining scientific techniques. This work will provide valuable data which will feed into future research agendas.  A total of 180 samples were retained for DNA analysis.

	<p>How can the analysis of dental remains contribute to the development of techniques for microscopic dental ageing methods and biochemical methods?</p>	<p>disinterment.</p> <p>It is assumed that a significant number of interments can be related to a surviving coffin plate. However, the disturbed nature of the material and the conditions and methods of working may limit the potential of recovering uncontaminated remains.</p> <p>The working assumptions are that sufficient appropriate samples of human remains will be available to meet the objectives within this topic. These objectives also relate to topic of preservation and taphonomy.</p> <p>The above assumptions regarding the potential apply.</p>	<p>topic.</p> <p>If model is correct, collect samples of human bones from non-sealed interments with biographical details: 4 (undamaged if possible) metacarpals or metatarsals, canine teeth, both lower if possible, upper if no, and two molars without carious lesions.</p> <p>Evaluate assumptions as above.</p> <p>If assumptions correct, collect dental samples from non-sealed interments with biographical details.</p>		
<p><b>The nature of funerary material culture (Topic 5/3)</b></p>	<p>What was the nature of the coffin decoration and what does this tell us about the treatment of the dead and the undertaking industry?</p>	<p>It is unclear how many coffin plates survive. Given the nature of the reinterment, the ethical considerations, preclude removal of plates, coffin furniture and grave goods. A record of the details of these, would however. Add to the general reference collection of funerary furniture for London in this period.</p>	<p>Written drawn and photographic records will be made on site.</p>	<p>Assess the potential against the taxonomy for coffin plate design in London.</p> <p>If potential confirmed analyse as appropriate.</p>	<p>New types have been identified. These should be compared with the range of types in extant Trade Catalogues. It should be possible to determine cost of coffin for a number of discrete inhumations.</p> <p>New types have been identified. These should be compared with the range of types in extant Trade Catalogues. It should be possible to determine cost of coffin for a number of discrete inhumations.</p>

## ST LUKE'S CHURCH, OLD STREET, ISLINGTON, LONDON EC1

### WRITTEN SCHEME OF INVESTIGATION

#### SUMMARY

*Construction and refurbishment works are planned to take place at the Grade I listed St. Luke's Church, Old Street, London, in order to provide new educational and rehearsal facilities for the London Symphony Orchestra. These works will entail clearance of post-medieval interments from the crypt and part of the churchyard. Part of the church will be underpinned, the structure of the crypt will be consolidated and the vestry will be cleared. Enabling works and the clearance of interments will be carried out as part of the same package. Necropolis has recently been appointed to carry out these works.*

*Measures are required to mitigate the impact of the proposed works on the surviving archaeology. This document outlines the archaeological proposals for doing so. Although post-medieval funerary deposits have the potential to yield a wide range of archaeological and historical information it is probable that the resource at St Luke's is likely to be incomplete and in poor condition. In addition the structural condition of the crypt is very poor. Both of the latter points impose constraints regarding health and safety and the potential of the resource. However, it will still be possible to answer questions relating specifically to the group buried at St Luke's. The resource is also likely to further our understanding of the taphonomy of crypts and churchyards and it may contribute to the development of techniques for the scientific analysis of human remains from funerary deposits.*

*For these reasons the resource does not merit full archaeological excavation. Therefore it is proposed to undertake an archaeological watching brief on the clearance of the human remains by a commercial undertaker, with specific objectives relating to the potential outlined above.*

#### 1 INTRODUCTION

##### 1.1 Location and topography

St Luke's Church, Old Street (NGR TQ 32320 82423), is a Grade 1 listed 18<sup>th</sup>-century church which today is a disused, roofless structure. The walls of the nave, vestry and tower, which is attributed to Hawksmoor, survive. Beneath the church there is a crypt, with a number of vaults or bays containing coffined human remains (Figure 2). The church lies within its churchyard, set back from the busy east-west running Old Street, within the London Borough of Islington, in the parish of St Giles without Cripplegate. It is bounded by Helmet Row to the west, Ironmonger Row to the east, Old Street to the south and Mitchell Street to the north. The site lies on the Third Terrace above the river Thames. Where it has not been quarried away, the underlying natural substrate is brickearth, overlying Thames terrace gravels. The site is flat and the present-day ground level is c 20.5 m OD.

##### 1.2 Archaeological and historical background

The church is located at the extreme north-west limit of the 'Moorfields Marsh' which is known to have been landfilled in the early post-medieval period. Accounts made at the time of the construction of the church mention marshy conditions (MoLAS 1996, 20). It was constructed as part of the Commission for Fifty New Churches, which was set up in 1711; at this time St Giles Cripplegate was reported to have 4600 houses. The church was consecrated in 1733. Repairs to the structure of the church were undertaken in 1734, 1869, 1877, 1914 and 1951. The building has been prone to subsidence and cracks are visible in the north and south walls. The church was built over a semi-subterranean crypt, constructed of brick as an integral part of the church structure. Although it was initially prohibited from use for burials the Vestry minutes first list fees by 1740. There are known to be both earthen and vaulted graves within the churchyard which has been landscaped. No headstones survive *in situ* but a small number of chest tombs remain. The chest tombs, railings and gate are listed Grade 2.

An archaeological watching brief was undertaken on five test pits excavated against the exterior walls of St Luke's in order to assess the composition and state of repair of the foundations to the church and the material in which they were constructed. It was not clear from the test pits whether the foundations to the church were constructed in a trench or whether the surrounding material was dumped later. No archaeological levels demonstrably earlier than the church were revealed. This investigation suggested that there are likely to be few inhumations in the immediate vicinity of the church. Inhumations were encountered in test pits 1 and 2, those in the former at a depth of only 0.8 m. Burial vaults were identified in test pits 2 and 3.

A desk-based assessment produced by MoLAS (Miles 1996) details all existing documentary sources. This was followed by an assessment of the archaeological potential of the site, particularly in relation to the study of post-medieval human remains, and the development of recommendations for archaeological mitigation (Cox 1997; 1998). A conservation plan for the site and building has recently been prepared by Purcell, Millar and Tritton.

## 2 DEVELOPMENT PROPOSALS

The St Luke's project involves the refurbishment of the church to provide rehearsal and educational facilities for the London Symphony Orchestra. Partial funding has been obtained from the Heritage Lottery Fund. The refurbishment work includes the underpinning of the external walls, the provision of a new roof, conservation of the structure and the clearance of the crypt and part of the churchyard to accommodate the construction of additional space at basement level. The work will impact on the archaeological resource in three ways:

- Human remains will be removed from the crypt and graveyard
- Construction work in the graveyard and crypt may disturb potential archaeological layers beneath the lowest burial levels
- The works will require disturbance to and the removal of some elements of the building structure, including the crypt

### 3 ETHICAL AND RELIGIOUS CONSIDERATIONS

The ethical and religious implications are of primary concern. All staff involved in the exhumation of the remains will be expected to behave with care and attention, showing respect for the dead at all times. The burials represent the remains of past parishioners of the church of St Luke and thus particular consideration will be afforded to the sensitivities of any individuals who have connections with St Luke's in all excavation and reinterment works. Thus all sealed lead coffins will remain sealed, will be sleeved on site and removed for reburial. Open or badly damaged coffins may be inspected by archaeologists subject to medical opinion.

### 4 LEGAL CONSIDERATIONS

The London Diocesan Fund holds the freehold for the St Luke's church and surrounding burial ground. As the church is now redundant, the exhumations will not require a Faculty. Rather, section 65 of the Pastoral Measure applies. For reasons of decency and dignity, the Church Diocesan Fund has stipulated that sealed coffins should not be opened and that such coffins should be sleeved on site and removed for reburial.

Home Office directions are required for the removal of buried human remains. A Home Office order has been granted for the exhumations at the St Luke's. The current Home Office order relating to the exhumation works (dated 21 January 1999) stipulates that the removal shall be subject to agreement with the Chief Environmental Scientist for the London Borough of Islington.

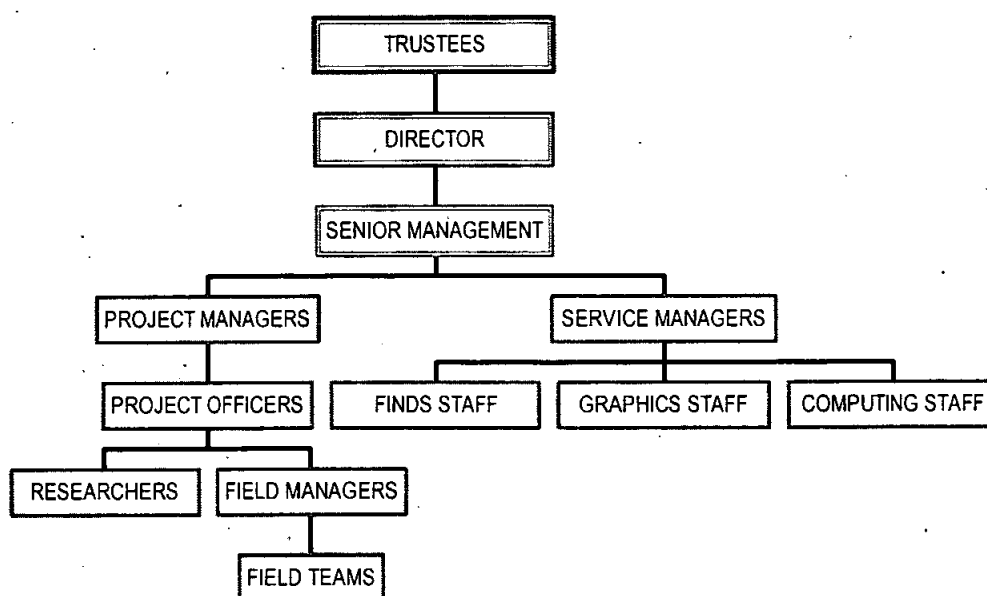

The Archaeological Contractor has responsibility to demonstrate that they have planned a safe working practice by providing the Planning Supervisor and Principal Contractor with a Risk Assessment and developed Health and Safety plan of all work to be done by the archaeological team, a current Health and Safety policy and the detailed specification for the archaeological watching brief.

The Health and Safety at Work Act 1974 under which the Personal Protective Equipment at Work Regulations are made will be complied with at all times by the Archaeological Contractor. Evidence of appropriate procedures will be detailed in the Risk Assessment.

## 5 PROJECT STRUCTURE AND OAU HIERARCHY

### 5.1 OAU Organisational structure

### OAU ORGANISATIONAL STRUCTURE

### 5.2 Project structure and personnel

Project Manager	Angela Boyle
Project Officer	Dave Score
Osteologist	Julie Roberts
Osteologist	To be named
Supervisor	Adam Brossler
Coffin furniture specialist	Melanie Richmond
Crypt recording and tombstones	Ric Tyler
Computer data entry	Mark Peters
Documentary Research	John Chandler
Database set-up	Niall Donald
Surveying of churchyard	Mark Lacey
Technicians	To be named

The Project Manager, Angela Boyle, will be on site for part of the excavation and will liaise with all of the main parties. She will be available at all times to discuss progress with the Archaeological Consultant. The Project Officer will be responsible for all the aspects of the on-

site implementation of the archaeological work, and co-ordination with the Enabling Contractor and other parties. At least one supervisor will assist the Project Officer and will have particular responsibility for stratigraphic recording. The senior osteoarchaeologist, Julie Roberts will be on site full time to undertake all aspects of the recording of human remains, either *in situ* or after lifting. A second osteologist will be appointed to assist on the project. The artefacts co-ordinator, will have particular responsibility for ensuring that all coffin fittings are adequately catalogued *in situ* and for full identification and recording. Building recording and photography will be undertaken by Ric Tyler.

A further two skilled archaeological excavators (none with less than 2 years continuous fieldwork experience) will be available as required for the duration of the works. Only staff with previous experience of burial archaeology have been chosen to work on the project.

Curriculum Vitae for all named staff can be found in Appendix 1.

## 6 POTENTIAL

### 6.1 Research issues in post-medieval archaeology

Research issues in post-medieval archaeology were recently defined in some detail (Reeve 1998, 222). It is clear that the relationship between the historical documentation and the condition of the material (both skeletal and artefactual) is a critical one.

- *Funerary archaeology*. Sub-headings include charnel pits, mass graves, artefact developments, taxonomies, social and gender archaeology, the English funeral, ownership and choice of vaults, burials as entities, graveyard methodology, location of interments to memorials
- *Osteoarchaeology*. Sub-headings include palaeodemography and demography, biological anthropology, pathology, epidemiology, osteological methodology (pathology, age and sex, stature), forensic science, clinical medicine, genealogy
- *Archaeological methodology*. Theory and practice, curation procedures and environments
- *Evidence for known historical events*, eg epidemics

Very little systematic recording of crypt populations or indeed post-medieval graveyards has taken place. Although several clearances have been carried out at London churches only Christ Church, Spitalfields has been subject to detailed archaeological and osteological recording in conjunction with extensive documentary research.

### 6.2 Completeness

The completeness and integrity of the human skeletal assemblage has been affected by disturbance to the crypt by vandals and grave robbers, thus the potential for detailed population studies is severely limited. Furthermore the construction work in the churchyard will involve only partial exhumation of the burials there.

### **6.3 Condition**

Conditions within the crypt are very damp and this is likely to have caused the decay of wood, textiles and other materials. Both the coffins and the human remains will have been affected by the activities of rodents, insects, bacteria and fungi. The successive layering of coffins one on top of another may well have crushed earlier burials.

It is likely that successive burial in the churchyard has led to intercutting and disturbance to all but the latest burials. The digging of drainage ditches and landscaping will also have affected the integrity of the deposits.

### **6.4 Rarity**

It is clear that other similar assemblages survive in London. Nonetheless the anticipated size of the sample combined with the existing documentary evidence do enhance the rarity and potential of the group.

### **6.5 Historical documentation**

A wide range of documentary evidence exists and this will enhance and complement the archaeological information.

### **6.6 Group value**

The value of the group is likely to be moderate due to the incomplete nature and poor preservation of the assemblage. However, the evidence for this is unclear and remains to be demonstrated by the proposed archaeological intervention. If preservation is as poor as is anticipated it will still be possible to determine basic demographic parameters by employing low-resolution osteological recording. This will facilitate comparisons with similar groups from London and elsewhere.

### **6.7 The crypt structure**

Although the structural condition of the crypt is poor, examination and recording can provide information relating to the original structure and subsequent modifications to it.

## **7 HEALTH AND SAFETY**

Funerary archaeology presents a specific and complex range of hazards. The risk of anyone contracting smallpox is remote but the potential threat to the population at large is such that it must be taken seriously. All staff will wear protective clothing at all times (see outline risk assessment).

Where wooden coffins were used there may be an increased risk of infection due to occasional good preservation of bodies and other materials. The highest risk category is that of the sealed lead coffins. If any soft tissue remains the hazard presented will be treated as potentially severe and

suitable protective systems will be used. It is not only the human remains themselves that present a risk but also the coffin linings and pads; and the result of the body's decomposition, a viscous black liquid. The greatest potential risk presented by this activity is that of contracting anthrax or smallpox. The risk for the archaeologist associated with working with the remains of a recorded anthrax death are thought to be small. A higher risk is gained from the well-preserved horse hair or woollen materials used in the coffin pads, pillows and packing (see outline risk assessment).

Minimum precautions are to wear the correct level of protective equipment. In addition all staff must have a primary inoculation scar. Shower facilities will be provided by the Enabling Contractor for all staff.

There is a possibility of increased lead levels in blood due to the concentration of lead in the atmosphere. Constant monitoring of the health of the workforce will be required for the duration of the work

## **8 RESEARCH AGENDA AND OBJECTIVES AT ST LUKE'S**

A number of assumptions have been made regarding the nature of the archaeological resource at St Luke's.

- Very few of the coffins remain sealed and therefore a significant proportion of the interments will survive largely intact but without soft tissue or other organic remains such as textiles.
- A significant proportion of interments will have biographical data in the form of coffin plates

If these assumptions are correct then it can be argued that the resource does have the potential to address a limited number of research objectives.

- Development of the crypt and graveyard through time by discussion of stratigraphy and formation processes on site
- Enhancement of our understanding of post-medieval funerary contexts and the archaeological techniques employed
- Enhancement of osteological techniques through the study of individuals of known age and sex
- Development of our knowledge of funerary rites and the treatment of the dead
- Analysis of the construction, use and modification of the crypt structure

## **9 PROPOSED AIMS**

The aim of this archaeological excavation is to record and interpret as much detail as possible within the parameters of a relatively rapid exhumation and reinterment exercise. The archaeological data collected will contribute to the history and development of funeral trends and the demography of the population of the crypt and that part of the graveyard which is being disturbed.

The objectives of the archaeological work will be to record the preservation conditions within the crypt and churchyard, the inscriptions on coffin plates, and recording of the human remains and limited sampling of human skeletal remains with biographical data. The crypt structure will also be recorded. The objectives the archaeological work will be to record the preservation conditions within the crypt and churchyard, the inscriptions on coffin plates, and recording of the human remains and limited sampling of human skeletal remains with biographical data. The crypt structure will also be recorded.

- Archaeological watching brief on the clearance of the crypt, recording the number of interments, the biographical data on coffin plates and the position of each interment. Any design motifs visible on coffin furniture should also be recorded.
- The creation of a database of the inscriptions and assessment and analysis of the inscriptions data.
- The recording of the human remains prior to their removal by the commercial undertakers.
- Archaeological recording of the graveyard landscape, to identify the appearance of the original landscape, to recover and analyse the soil around interments and to record the number of interments.
- Archaeological recording of the crypt structure.
- Investigation and recording of any archaeological remains beneath the lowest burial levels in areas of the graveyard to be affected by construction works. The likelihood for this is believed to be low.
- The collection of samples of human bone for analysis by Bournemouth University
- Documentary research to enhance and augment information recovered during the Watching Brief.
- Post-excavation analysis of all material with the exception of the samples of skeletal remains, and assessment of data in relation to the research issues detailed in the *Project Design for Archaeological Mitigation*
- Full reporting to the standards set out in the *Project Design for Archaeological Mitigation*,
- Proposal for a "Popular" publication.
- To collect data which will contribute to the understanding of the history and development of funeral trends.
- To collect data which will contribute to the understanding of the demography of the population of the graveyard which is being disturbed.
- To establish the stratigraphic sequence of burials.
- To record vault structures and their contents in detail.
- To identify any existing evidence for pre-crypt activity.
- To provide dating evidence for the surviving burials.
- To recover evidence of burial rites and undertaking practices.
- To determine the character and date range of the burials

## 10 PROPOSED METHODOLOGY

All memorials, burials, in whole or part, vaults and other archaeology will be identified and recorded in the clearance area. A scheme for the minimum appropriate level of the recording and treatment of all of the following has been designed:

- Stratigraphic relationships
- All archaeologically significant remains other than burials
- Vaults - full structural record
- Gravestones - full textual and photographic record
- Human remains - state of preservation
- Lead coffins
- Funereal architecture
- Funereal furniture
- Funereal artefacts
- Biographical information
- Osteological details - non intrusive: age, sex, gross pathology, trauma and disease

### 10.1 Excavation techniques

A site grid covering the area of investigation will be established. The grid will be at a scale appropriate to the confined nature of the crypt. Within the churchyard a 5 m grid will be most appropriate. A temporary bench mark related to Ordnance Datum will be created.

#### 10.1.1 Proposed recording system

A single context recording system will not be appropriate in this circumstance. Therefore, the focus of recording will be the skeleton. Each interment will be assigned a unique number from a continuous running sequence. The same number will be assigned to the coffin and any associated fittings. This system was applied successfully during the archaeological watching brief at St Bartholomew's, Penn, Wolverhampton which was carried out by the OAU in attendance upon Necropolis. During this project 400 post-medieval burials were removed over an eight-week period.

Preservation and completeness of skeleton will be recorded *in situ* prior to osteological analysis. It is proposed that bagging of skeletons will only be undertaken after osteological analysis is complete. Specialised recording forms will be available for the recording of both coffins and skeletons (see Appendix). Charnel and disarticulated remains will not be recorded although they will be carefully cleared from all spoil prior to its disposal by the Enabling Contractor.

Written descriptions will be recorded on proforma sheets comprising factual data and interpretative elements. Examples of the OAU recording sheets appear in the Appendix. A Harris matrix will be compiled during the course of the excavation.

All data will be computerised as the excavation progresses.

#### 10.1.2 Plans

Measured plans of the churchyard and the crypt will be produced at a scale of 1:50 and all burials will be located on it. Individual skeletons and coffins will not be planned as provision will be made for photographic recording as deemed appropriate. The site grid will be accurately tied into the National Grid and located on the 1:2500 or 1:1250 map of the area. A register of plans will be kept.

### **10.1.3 Sampling strategies**

Soil samples will be taken during works within the churchyard in order to characterise the nature of the burial environment.

### **10.1.4 Coffins and coffin fittings**

Wooden and lead coffins and any associated fittings, including nails, will be recorded on the coffin recording sheet. All surviving coffin fittings will be recorded in detail by reference to the published corpus of material from Christ Church, Spitalfields (Reeve and Adams 1998) as well as the unpublished catalogue of material from St Nicholas, Sevenoaks (Boyle 1994) and St Bartholomew's, Penn (in preparation). Where individual types cannot be paralleled they will be drawn or photographed as appropriate.

### **10.1.5 Photographic policy**

A black and white and colour (35 mm transparency) photographic record, illustrating in both detail and general context will be maintained. The photographic record will also include working shots to illustrate more generally the nature of the archaeological work. A colour slide lecture set will also be compiled. A photographic record of the chest tombs will be made prior to their removal. Photographs will be recorded on OAU Photographic Record Sheets.

## **10.2 Osteological recording methodology**

The skeletal assemblage will be divided into high- and low-resolution samples. The high-resolution sample will consist of named individuals (particularly related individuals) and those of intrinsic osteological interest. The latter can be defined as those with unusual pathology, evidence of surgical or dental intervention and exceptionally good preservation. Low-resolution skeletal recording will include a skeletal and dental inventory, age and sex assessments, gross pathological observations, and basic metrical recording for use in the determination of stature and sex. The high-resolution sample will be subject to the same recording criteria with the addition of detailed descriptions of pathological manifestations and differential diagnosis, additional metrical recording, and a study of non-metric traits. The aim of the low-resolution analysis is to provide enough information to reconstruct the demography of the excavated sample *in toto*. Similar methodologies were applied to the skeletal assemblages from St Nicholas, Sevenoaks (Boyle 1998), London Road, Kingston-upon-Thames (Bashford and Pollard 1998; Start and Kirk 1998) and most recently at St Bartholomew's, Penn, Wolverhampton (Boyle in preparation).

It will probably not be necessary to wash the skeletal material and dry brushing is proposed instead. Possible exceptions to this will include remains of particular pathological interest, particularly if photography is required.

### 10.3 DNA analysis

Samples for DNA analysis will be recovered from all named individuals in the churchyard and crypt. For DNA analysis four metatarsals or metacarpals (preferably undamaged) and two molars (preferably non-carious) will be required. For ageing, 2no. lower canines or upper canines if lower canines are not available, will be required.

It is important that contamination of the samples required for DNA analysis is avoided. All staff involved in the extraction of samples will be gloved, masked and wear hooded disposable overalls. Sealed containers for the samples and a freezer capable of storage of samples at below -20 degrees centigrade will be provided.

### 10.4 Osteological aims

- To establish the biologically determined demographic structure of the sample.
- To assess the inter-relatedness of the group through biological methods.
- To investigate and interpret pathological manifestations and patterns within the sample.
- To compare the biological assessment of the sample with the historical picture of the group provided by documentary sources.
- To provide a detailed record of the skeletal group prior to its reinterment

### 10.5 Demography

Probable age and sex can be assigned to each individual. This will allow for comparison of this group with other contemporary samples. The excavated burials will represent only a small percentage of the burial population. The basic parameters of a demographic investigation are age and sex, and these will be established for all excavated individuals in the course of low-resolution analyses.

#### 10.5.1 *Sex estimation*

Standard osteological techniques will be used in the multi-factorial assessment of biological sex (Steele and Bramblett 1988; Buikstra and Ubelaker 1994). Individuals will be assigned to probable male, probable female or unknown categories where incompleteness, poor preservation, or ambiguous results prohibit definitive assignment to either sex.

#### 10.5.2 *Age estimation*

Standard osteological techniques will be used in the establishment of age at death (Miles 1962, 1963; Lovejoy *et al* 1985; Buikstra and Ubelaker 1994).

## 10.6 Vaults and lead coffins

A structural record of the vaults will be compiled. Elevations and plans will be drawn, brick-types, manner of construction and bonding will be recorded. The vaults will be dismantled by the Enabling Contractor and their contents will be recorded archaeologically. Where lead coffins survive intact these will be lifted by the Enabling Contractor and sleeved in preparation for reburial. Only external features of sealed lead coffins will be recorded archaeologically. Where lead coffins are damaged or broken they will be recorded by the osteoarchaeologist and subsequently removed by the Enabling Contractor.

## 10.7 Crypt recording methodology

### 10.7.1 *The written record*

Written descriptions will be made of each individual context identified during the survey using pro-forma context recording sheets (see Appendix 2). Data recorded will include context type and, as appropriate, materials, dimensions, composition, 3-dimensional co-ordinates, together with a summary interpretation of the context as free text. Context numbers will be assigned for each distinct, identifiable feature within the structure. In this context, the term 'feature' is used in the sense of any distinct element of the structure with distinguishing, quantifiable characteristics. Thus, any area of masonry employing a distinct mortar type or building stone will be assigned a unique context number. Group numbers will be assigned for ease of reference, thus a wall comprising a number of different individual contexts may be referred to either by its component contexts or by a 'group number' as appropriate.

### 10.7.2 *The drawn record*

An overall plan of the crypt will be made at a scale of 1:20/1:50 as appropriate and related to an independently established site grid and cross referenced where possible to existing surveys of the church.

Sufficient representative longitudinal and transverse cross sections will be drawn at a scale of 1:20/1:10 as appropriate. Cross-sections will be related to independently established horizontal datum lines and will be cross referred to Ordnance Datum and to the independently generated plan (see above).

As necessary, and in particular where fabric is to be removed during works, detailed wall elevations will be drawn at a scale of 1:20/1:10 related and to the independently generated plan (see above). Particular attention will be made to significant changes in fabric (walling material/mortar etc) where these can be shown to relate to the development of the structure.

All site drawings will be made in pencil on archivally stable drafting film.

All site drawings to be digitised and stored as AutoCAD R14 \*.dwg files.

### 10.7.3 *The photographic record*

A full colour and black and white photographic survey of the crypt will be made. This will comprise two principal elements; large and/or medium format general and contextual views augmented by full 35mm coverage during works.

Medium format black and white and colour negative photographs of the overall appearance of the crypt will be taken (as appropriate) before the commencement of work, once the surface coffins have been removed and upon completion of works. This record will be supplemented by a full 35mm black and white negative and colour transparency photographic record of significant architectural structures (including discrete vaults) and details as exposed throughout the course of works.

Large and medium format photography to be undertaken by Mr David Stevens of The Downland Partnership. Images to be supplied as high resolution \*.TIFF images on CD-ROM.

## 10.8 *Biographical database*

A database for the recording of all biographical data will be constructed for data entry on site. The database will consist of tables describing five entities: coffins, coffin fittings, human remains, inscriptions and biographies.

### 10.8.1 *Coffins*

The coffins table will contain the following fields:

*Coffin Unique Identifier (Primary Key)*

*Coffin type*

*Coffin condition*

*Presence or absence of textiles*

*Count of the original Number of Fittings By Fitting Type*

### 10.8.2 *Coffin fittings*

The Coffin Fittings table will allow the description of the surviving individual coffin fittings for each coffin. It will consist of the following fields:

*Fitting Unique Identifier (Primary Key)*

*Coffin Unique Identifier (Foreign Key)*

*Fitting Type (coffin grip, coffin plate, grip plate, lid motif, escutcheon, upholstery pins)*

*Fitting Value (the classification value for the particular Fitting Type)*

*Material (the material from which the fitting is made)*

Fitting Values will be validated by reference to the classifications published in *The Spitalfields Project, 1993, Jez Reeve and Max Adams, CBA Research Reports* and will allow the definition of new values as required by the situation at St Luke's Church.

### **10.8.3 Inscriptions**

The Inscriptions Table will allow the description of coffin inscriptions and will contain the following fields.

*Inscription Unique Identifier (Primary Key)*

*Coffin Unique Identifier (Foreign Key)*

*Forename*

*Initial*

*Surname*

*Date of Birth*

*Date of Death*

*Age at Death*

*Sex*

*Inscription Text*

### **10.8.4 Human remains**

The Human Remains Table will contain the following fields:

*Remains Unique Identifier (Primary Key)*

*Coffin Unique Identifier (Foreign Key)*

*Preservation (scale 1-4)*

*Completeness (scale 1-4)*

*Osteological Age*

*Osteological Sex*

*Femoral Head Measurement*

*Stature*

*Third Molar Absent*

*Ante Mortem Tooth Loss (value between 0 and 32)*

*Caries (a value between 0 and the value of the number of surviving teeth)*

*Abscesses (a value between 0 and the value of the number of surviving teeth)*

*Pathologies (validated by a list of possible pathologies)*

*Presence or absence of Non-metric values*

### **10.8.5 Biographies**

The biographies table will describe the data collected from the analysis of the parish registers and will contain the following fields

*Biography Unique Identifier*

*Forename*

*Initial*

*Surname*

*Gender Status ("man", "woman" or "child")*

*Cause of Death*

*Place of Burial*

*Age*

*Address1*

*Address2*

*Social Status ("pensioner", "workhouse")*

*Relations*

*Marital status*

## **10.9 Tools and equipment**

All mechanical plant and large equipment of whatever type, other than hand tools, surveying and photographic and computer equipment, is to be provided, and operated by the Enabling Contractor, where necessary under the instruction of the Archaeological Contractor. This will include all mechanical excavators, hoists, elevators, cranes, skips etc. All shoring and its manipulation will be the total responsibility of the Enabling Contractor. The preferred method will allow for the maximum working areas throughout.

## **10.10 Site facilities**

A site office is to be located within the main fenced area, or as near to the excavation area as possible, for use by the osteoarchaeologist and finds co-ordinator for the on-site recording of all human remains and coffin fittings.

A mess facility, site office, appropriate washing facility and sufficient serviced portaloos (at a ratio of one per 10 individuals) to be provided for the dedicated use of the archaeological team.

The provision, location/relocation and servicing of all site facilities as described above, to be provided by the Enabling Contractor for the duration of the archaeological work. All facilities are to be appropriately furnished for their intended usage and heaters/lighting to be provided if required by the Archaeological Contractor.

## **10.11 Removal of topsoil and initial grave overburden**

Removal of all topsoil and grave fills in the churchyard to uppermost levels of articulated remains (ie not including disturbed charnel) to be the responsibility of the Enabling Contractor under supervision of the Archaeological Contractor. Where machining is not possible then the Enabling Contractor will be responsible for the hand-removal of the spoil and initial grave overburden. The Enabling Contractor will be responsible for the removal of disarticulated remains from this spoil prior to its disposal. Removal of later of spoil within the crypt is also the responsibility of the Enabling Contractor.

## **10.12 Comparative reference material**

There are a number of published excavation reports which will be of particular relevance to this project. These include Christ Church, Spitalfields (Reeve and Adams 1993; Molleson and Cox 1993), St Nicholas, Sevenoaks (Boyle 1994; Boyle 1998, Boyle in press), London Road, Kingston-

upon-Thames (Bashford and Pollard 1998; Start and Kirk 1998), and St Bride's Church, Fleet Street, London (Scheuer 1998). A number of other relevant articles have also been published in a recent monograph dedicated to the study of post-medieval burial (Cox 1998). Work is currently in progress on the graveyard of St Bartholomew's, Penn where the OAU recently undertook an archaeological watching brief in conjunction with Necropolis (Boyle in preparation). The crypt population is contemporary with Christ Church and likely to be more representative of the indigenous population.

## **11 PROJECT CONSTRAINTS**

The nature of the excavation demands that the whole process is undertaken out of the site of casual observers. To this end hoardings will be erected by the Enabling Contractor who will also be responsible for their maintenance and removal.

### **11.1 Security**

Site security will be rigorous. A signing-in system will be put in place ensuring that the presence of all those on site at any time will be recorded. Casual visits to the excavation will not be permitted. Necropolis will be responsible for the provision of 24 hour security from the commencement of the project.

### **11.2 Publicity**

Due to the sensitive nature of the excavations no access will be given to media representatives (from any source). However, both Necropolis and OAU will liaise with those members of the general public who overlook the site. Photographs of the excavation will be for archaeological purposes only.

### **11.3 Hygiene**

Strict adherence to the site Health and Safety policy produced by Necropolis will be observed at all times. Personal protective clothing, worn on site must not be worn outside the compound area. Mess, sanitary and washing facilities will be provided by the Enabling Contractor.

### **11.4 Reinterment**

During the course of the excavation, human remains will be removed for reinterment in the East London cemetery. Human remains will be reburied with associated coffin furniture and biographical details where they exist. The Enabling Contractor will provide on-site storage with secure lock-up facilities.

## **12 STANDARDS**

OAU shall conform to the standards of professional conduct outlined in the Institute of Field Archaeologists' Code of Conduct, the IFA Code of Approved Practice for the Regulation of Contractual Arrangements in Field Archaeology, the IFA Standards and Guidance for Field Evaluations, Desk Based Assessments, etc. and the British Archaeologists and Developers Liaison Group Code of Practice.

OAU is a member of the Institute of Environmental Assessment and the Council for British Archaeology.

For more extensive and complicated evaluation projects especially where they are part of large-scale programmes of work in historic urban centres, the procedures outlined in English Heritage's *Management of Archaeological Projects* 2nd Edition 1991 (MAP 2) will be followed for immediate post-field archive preparation and initial assessment. Agreement will then be reached, in collaboration with the local authority's archaeological representative, about what aspects will need to be taken forward to provide a report in the required format containing the information needed for planning purposes.

All works shall be carried out in accordance with Archaeological Guidance Papers *Standards and practices in archaeological fieldwork in London*, *Archaeological reports*, and *Post-excavation assessment and updated project design* (English Heritage 1998) and the Institute of Field Archaeologists *Standards and guidance for archaeological investigation and recording of standing buildings or structures* (IFA 1999).

All contact with the client and with English Heritage GLAAS will be through WS Atkins Heritage.

### 13 POST-EXCAVATION ANALYSIS AND REPORT WRITING

The importance of the archaeological remains will be determined during the watching brief. A detailed report will be compiled which will provide all quantitative data sorted by skeleton number, appropriate plans and sections, followed by analysis and interpretation of the results. This will include discussion under the following themes:

- Management of the crypt and the graveyard through time - discussion of the stratigraphy
- Tombs and other built structures
- Coffins and coffin furniture
- Treatment of the dead
- Individuals with biographical information from stones and coffin plates
- Individuals without biographical information
- Development of the church and the use of the site
- Osteology

Generation of phased 'development' plan of crypt based upon evidence recorded during clearance of the crypt. This to take into account dating evidence from coffin data and attempts

being made to reference identified events to known campaigns of refurbishment undertaken at the church (1734, 1869, 1877, 1914 and 1951).

#### **14 STATEMENT OF CO-OPERATION BETWEEN ARCHAEOLOGICAL CONTRACTOR AND NECROPOLIS**

The following paragraphs will form part of a Statement of Cooperation to be agreed by the archaeological contractor and Necropolis, following selection of tenders. This statement will be issued for approval to the Archaeological Advisor to Islington Borough Council.

It is imperative that the project is completed according to programme in order to remain within the budget and to attract the funding package that has been arranged. Due to the large size of the site, it is anticipated that there will be multiple working areas operating at any one time. This should enable the archaeologists to examine remains for sufficient periods of time, without disruption to the programme. However, it is also important to note that complete stoppage of the works due to archaeological activities is limited to three hours per incident, unless otherwise agreed by the client.

The requirements of the archaeological recording will take precedence over the commercial exhumation contractor's work. Following selection of tenders, a statement of working methods will be prepared jointly between Necropolis and the selected archaeological contractor. This will include details of measures regarding health and safety as well as details on the integrated working methods.

##### **14.1 Sealed coffins**

It is anticipated that there will be very few fully intact sealed coffins, due to the environmental conditions, time and vandalism. Each coffin will be inspected prior to lifting. Where coffins have already been perforated due to collapse, oxidisation or vandalism, the decency of the occupant

**WS Atkins**

has already been compromised, and remains may be recorded by archaeologists and appropriate samples taken. In the unlikely event that some coffins remain fully intact, irrespective of whether they are sealed or not, these coffins will not be opened. If during lifting, it becomes apparent that the integrity of the decency of the deceased will be compromised, then the remains will be recorded by the archaeologists and appropriate samples taken.

##### **14.2 Working hours**

Necropolis have based their programme of works on a 6 day week, working 7.30 – 5.30. Arrangements may be made with the archaeological contractor for works not requiring archaeological supervision to be carried out while archaeologists are off site, but otherwise, an archaeological presence will be required at all times.

#### **15 THE STAGES OF THE EXCAVATION AND DATA COLLECTION**

## 15.1 Anticipated sequence of the enabling and exhumation works

The following are the principal activities of Necropolis which relate to archaeology. The sequence of these activities is subject to finalisation. Column 1 indicates the task to be undertaken by Necropolis. The archaeological response appears in column 2 with questions and objectives outlined in column 3.

NECROPOLIS	OAU	TOPIC	QUESTIONS/OBJECTIVES
<i>Phase 1</i>			
Site establishment and erections of hoardings	Create measured base plan of churchyard	Topic 6	
Dismantling and storage of railings and chest tombs from the churchyard	Record and photograph chest tombs in full prior to dismantling	Topic 6	Who was buried at St Luke's? How many people were buried at St Luke's?
Removal of a number of trees	Locate and record all exposed burials. Record preservation conditions, in particular root disturbance	Topics 1/2/6	How has the landscaping, in particular the planting of trees, affected the preservation of the interments within the churchyard?
Demolition of the vestry	No involvement envisaged		
Exhumation of the area adjacent to the north wall of the church	Locate and record all exposed burials and all associated coffins and fittings. Characterise burial environment	Topics 1/2/6	What is the character of the preservation environments at St Luke's?
Creation of a ramp on the north side of the church, leading from the crypt floor level up to the current surface of the churchyard.	Record exposed masonry. Produce full drawn and photographic record.	Topic 6	What was the original structure of the crypt and how was it modified?
Creation of access through the north wall of the crypt, using an existing opening, now sealed	Record and photograph area of north wall of crypt to be affected.	Topic 6	
<i>Phase 2</i>			
	As far as possible create base plan	Topic 6	
Creation of a north-south access route through the crypt and working area, by the creation of openings through the vault walls and by the clearance of surface coffins along this route.	Record masonry to be removed. Produce full drawn and photographic record. Record coffins and human remains.	Topic 4/6	Who was buried at St Luke's? How many people were buried at St Luke's?
Erection of shoring of the crypt structure	No involvement envisaged		
Machine clearance (of the rubble and debris) of the central access zone to create a working area.	No involvement envisaged		
Clearance of the main vaults and discrete vaults, of the surface coffins and human remains	Record coffins and human remains. Locate burials on base plan.	Topic 2/4	Who was buried at St Luke's? How many people were buried at St Luke's?
	Augmentation of base plan of crypt. Record cross-sections and longitudinal sections. Full photographic recording of discrete vaults.	Topic 6	
Exhumation of the churchyard area adjacent to the south wall of the church.	Record coffins and human remains. Record any existing structures. Locate both on base plan.	Topic 4	Who was buried at St Luke's? How many people were buried at St Luke's?
<i>Phase 3</i>			
Excavation of the crypt floor and trial pits below the floor	Record coffins and human remains. Watching brief for identification of any below ground structures.	Topic 4	Who was buried at St Luke's? How many people were buried at St Luke's?
Excavation of the crypt to formation level	Watching brief to determine presence/absence of remains predating St Luke's	Topic 7	
Excavation and clearance of spoil from the south churchyard	Watching brief to determine presence/absence of remains predating St Luke's	Topic 7	Was the church founded on the Moorfields Marsh landfill? What activity was there on the site prior to

			the landfill?
Shoring of the church and the faces of the retained ground	No involvement envisaged		
<i>Phase 4</i>			
Exhumation of the north churchyard	Record coffins and human remains. Record any existing structures Locate both on base plan.	Topic 4	Who was buried at St Luke's? How many people were buried at St Luke's?
Underpinning of the north wall	Record coffins and human remains	Topic 4	Who was buried at St Luke's? How many people were buried at St Luke's?
<i>Phase 5</i>			
Excavation and clearance of spoil from the north churchyard	Watching brief to determine presence/absence of remains predating St Luke's	Topic 7	Was the church founded on the Moorfields Marsh landfill? What activity was there on the site, prior to the landfill?
Shoring to the church and faces of retained ground	No involvement envisaged		

The above is not an exhaustive list of questions to be asked.

***Phase 1: item 1      Site establishment and erection of hoardings***

Create measured base plan of churchyard using EDM.

***Phase 1: item 2      Dismantling and storage of railings and chest tombs from the graveyard.***

Action: Photographic and/or drawn record of 10 chest tombs and a single row of repositioned flat stone monuments.

It is understood that the recording of the Grade II listed railings and gate prior to dismantling is to be undertaken by the project architects. Thus, no archaeological input is envisaged for this element of work.

The extent of proposed work in relation to the chest tombs within the graveyard is not specifically stated within the tender documentation. However, it is apparent that the churchyard contains a number of high quality monuments of this type, at least one of which is Grade II listed (the Caslon tomb - ref. 635-1/75/1) and it is understood that the total number of monuments concerned is between five and ten.

The level of recording required will necessarily depend upon the complexity and preservation of the individual monuments. However, a level 3/4 photographic record (as defined by the Royal Commission for Historic Monuments: *Recording Historic Buildings: a descriptive specification: 1<sup>st</sup> edition* RCHM 1990) of the monuments in context would seem appropriate in combination with a drawn record of significant details exposed during the dismantling process.

An RCHM level 3/4 photographic record covers the following subjects:

- The buildings overall external appearance. In the case of a building designed by an architect or intended to be seen from a certain point of view, it is important to have regard to the builders intentions and to record the effect of the design or of the buildings placing.

- Any external detail, structural or decorative, which is relevant to the buildings design, development and use and which does not show adequately on general photographs.
- The buildings relationship to its setting, to other buildings, or to a significant viewpoint.
- The overall appearance of the principal rooms and circulation areas, so far as possible recreating the lighting conditions in which they would have been used.
- Internal detail, structural and decorative, which does not show adequately on general photographs.

The record before dismantling will comprise medium format black and white negative and/or colour negative photographs, the record being supplemented by 35mm coverage during the dismantling process.

If required, rectified (scaled) photographs of the monuments may be produced (additional cost).

***Phase 1: item 3      Removal of a number of trees***

This task may afford the possibility of recording exposed burials and any associated coffins and fittings. In addition the preservation conditions will also be recorded.

***Phase 1: item 4      Demolition of the vestry***

It is understood that full recording of the Vestry will be undertaken by the project architects. Thus, no archaeological input is envisaged for this element of work.

***Phase 1: item 5      Exhumation...adjacent to north wall***

Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

***Phase 1: item 6      Creation of ramp... against north side of church..***

Photographic and drawn record of exposed masonry of north wall including nature of materials and phasing of blocked openings etc.

***Phase 1: item 7      'Creation of access... using existing opening now blocked'***

Photographic and drawn record of exposed masonry of north wall including nature of materials and phasing of blocked openings etc.

***Phase 2: item 1      '.. the creation of openings through the vault walls..'***

Photographic and drawn record of exposed masonry of north wall including nature/materials and phasing of blocked openings etc. Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

**Phase 2: item 4**      *'Clearance of the main vault and discrete vaults, of the surface coffins and human remains.'*

Base plan of crypt

so far as is practical, an overall plan of the crypt will be made before the removal of surface coffins to such level of detail as will allow for an accurate base plan of the location of the coffins during clearance.

Subsequent to Phase 2; item 4

Drawn record of crypt

The generation of overall record drawings of the crypt will be undertaken following the removal of surface interments. This to be in the form of fully measured plan, elevations, longitudinal and transverse cross-sections as appropriate. Elevation drawings to indicate significant changes in fabric related to the phasing of crypt.

The confined nature of the crypt, assumed from available information to comprise four parallel brick barrel vaults c.4 m wide x 25 m long suggests that the most feasible solution to planning would be the establishment of independent grids on a 2 m grid for each separate vault. The rectilinear form of the crypt and the apparent limited access between individual vaults would suggest that traditional manual survey techniques may be most suitable to generate the measured plans and cross sections, these being related to the independently established grids. This survey is to be cross referenced to existing architects' surveys.

The methodology for the survey of the vault will need to be reviewed and refined once the vault interior is accessible.

Discrete vaults will be subject to full drawn recording in advance of clearance.

Photographic Record

A full colour and black and white photographic survey of the crypt will be made. This will comprise two principal elements; large and/or medium format general and contextual views augmented by full 35mm coverage during works.

Medium format black and white and colour negative photographs of the overall appearance of the crypt will be taken (as appropriate) before the commencement of work, once the surface coffins have been removed and upon completion of works. This record will be supplemented by a full 35 mm black and white negative and colour transparency photographic record of significant architectural structures (including discrete vaults) and details as exposed throughout the course of works.

### Written Record

Written records will be made of the exposed crypt structure and associated discrete vault structures, special attention being made to construction techniques (brick bonding, visual appraisal of mortar etc.), materials (including surface treatments) and form, so as to allow comparison between structures. Records of discrete vaults to be cross referenced where appropriate to associated dating evidence from coffin data.

#### ***Phase 2: item 5      Exhumation.....adjacent to south wall of church***

Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

#### ***Phase 3: item 1      'Excavation of the crypt floor and trial pits below the floor'...***

Although necessarily an unknown quantity at this stage, the possibility of below floor architectural structures (for example, transverse inverted foundation arches on the line of the arcade bays) should be borne in mind. Such features would require written, drawn and photographic recording upon completion of works.

Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

#### ***Phase 3: item 2      Excavation of the crypt to formation level***

Although necessarily an unknown quantity at this stage, the possibility of below floor architectural structures (for example, transverse inverted foundation arches on the line of the arcade bays) should be borne in mind. Such features would require written, drawn and photographic recording upon completion of works.

#### ***Phase 3: item 3      Excavation and clearance....south churchyard***

Watching brief for any deposits which pre-date the use of the site as a church. Characterise soils and determine depth of natural.

#### ***Phase 4: item 1      Exhumation of the north churchyard***

Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

#### ***Phase 4: item 2      Underpinning of the north wall***

Locate and record all exposed burials and all associated coffins and fittings, Characterise burial environment. Where appropriate collect samples for DNA analysis.

**Phase 5: item 1      Excavation and clearance.....north churchyard**

Watching brief for any deposits which pre-date the use of the site as a church. Characterise soils and determine depth of natural.

**15.2 Programme**

The enabling works are to be undertaken over a period of approximately 25 weeks. On-site data collection will be limited to the shortest time that is reasonably possible. Necropolis have based their programme of works on a 6 day week, working 7.30 – 5.30. Arrangements may be made with the archaeological contractor for works not requiring archaeological supervision to be carried out while archaeologists are off site, but otherwise, an archaeological presence will be required at all times. OAU proposes a 5 day working week with on-site hours from 8.00-5.00.

**16 BURIAL NUMBERS**

It is possible that the number of burials predicted in the brief - ie 1900 (1000 in the churchyard and 900 in the crypt) - may be an understatement, given the limited extent of available data. Any significant difference between the actual buried numbers and those predicted may have a significant affect on both the duration of the work and the resource levels required and therefore the cost of the work.

In the event that a much greater number of burials are encountered than has been predicted for the purpose of this tender preparation, the Archaeological Contractor will have two alternatives: either to reduce the recording level in consultation with the Archaeological Consultant to a mutually agreed lack of resolution, which will keep the project on track in terms of programme and resources, or for a financial variation to be agreed to allow additional work to be undertaken. This could take the form of extra personnel over a longer period of time than originally programmed or for more staff to be added to the team to ensure completion within the agreed timetable. The latter alternative is likely to be the best approach.

While it would be inappropriate at this stage to determine a burial number threshold above which a cost variation might be sought it is suggested that the Archaeological Consultant could ultimately make this decision in consultation with the Archaeological Contractor.

**17 UNFORESEEABLE DISCOVERIES**

Apart from the possibility that significantly greater numbers of burials may have to be excavated, recorded and removed that has been predicted, there also remains the albeit unlikely possibility that other unforeseeable remains are discovered which will have implications for the completion of the work to programme. In the event that such discoveries are made it is suggested that the Archaeological Consultant considers the priorities and instructs the Archaeological Contractor accordingly. This could also take the form of a cost variation or change in archaeological priorities.

## 18 PROVISION OF PPE

The Archaeological Contractor will be responsible for the provision of the appropriate Personal Protective Equipment (PPE) based on the safety plan/risk assessment. The Enabling Contractor will be responsible for the appropriate disposal of the used PPE on a regular basis.

## 19 THE ARCHIVE

The site archive (paper and photographic record, artefacts and environmental samples) will be prepared for long-term storage in accordance with *Guidelines for the preparation of excavation archives for long term storage* (Walker 1990 - UKIC) and *Standards in the Museum Care of Archaeological Collections* (Museums and Galleries Commission 1992).

Agreement will be sought for the fully indexed archive of the project to be deposited as a publicly accessible collection, having been first offered to the RCHME for security copying. The detailed report of the results will be part of this archive and two copies will be submitted to the local Sites and Monuments Record for inclusion in the County record.

## 20 PUBLICATION

### 20.1 Academic publication

An appropriately detailed synthesis of the work and the analysis of results (excluding osteological analysis) will be prepared in agreement with the Archaeological Consultant. The size of the document will obviously relate directly to the numbers of burials recovered. At present the cost of post excavation and publication is based on the projected total of 1900 burials. A summary will also be prepared for inclusion in the *Journal for Church Archaeology* and *Post-medieval Archaeology*.

### 20.2 Popular publication

The OAU is committed to a wider dissemination of information and is currently developing a integrated package of heritage publications to satisfy a broad spectrum of interests. This package includes exhibition design, guide books, leaflets and regularly updated internet pages.

The archaeological results of the St Luke's project are certain to provoke interest from local residents and other interested parties. A popular publication was produced on the assemblage from Christ Church, Spitalfields (Cox 1996) and it is envisaged that a broadly similar format and content would be most appropriate.

Enabling works and on site organisation will be carried out by the enabling works contractor. All plant and facilities will be supplied by the enabling works contractor.

## 21 DOCUMENTARY RESEARCH

### 21.1 The human remains

It is proposed that documentary research will be undertaken prior to the commencement of excavation. A range of sources will be consulted. These include parish and burial registers, vestry minutes and further documentation referred to below.

The parish registers and burial registers for the church are fairly comprehensive and burial registers exist for the whole period of use of the crypt (1740-1853). The burial registers include cause of death from their commencement in May 1733 through to the introduction of pre-printed forms at the end of December 1812. Therefore in conjunction with the civil death certificates, cause of death should be available for approximately 90 years of the period of use of the crypt. This information may allow for the testing of pathological diagnoses and the correlation between disease and skeletal remains. Addresses of the deceased appear in the burial registers from 1804 onwards. Age at death does not appear until 1804 nor do the burial registers include details of location for most of the period of use. The legibility of the Registers is variable

The GLRO holds a *Register of headstones in back church yard c1753-1855* which records inscriptions on stones, name, person or family and plot number, also *Monumental inscriptions in St Luke's church yard* (1877) with an index.

The Vestry Minutes are held at the Finsbury Local History Library and they survive for the entire period of use. There is also a record of the stones and a plan of their location *after* removal made c 1937 when the graveyard was cleared and the stones relocated against the walls of the church. In addition there are tax returns, census returns, insurance policies, trade directories, company records, wills and probate records.

### 21.2 The crypt structure

A search of available secondary sources will be carried out.

See MoLAS report

- RIBA Drawings Library.
- Minutes of Commissioners for Building of 50 New Churches: Lambeth Palace Library.
- Finsbury Library Local Collection.
- Peculiar Jurisdiction of St Paul's Cathedral - Archivist / Library and/or Guildhall Library: Bishops Faculties.
- Blandford Street EH NMR

## 22 GENERAL

The requirements of the Brief will be met in full where reasonably practicable. Any significant variations to the proposed methodology will be agreed with the local authority's archaeological representative, the Archaeological Consultant and the client in advance.

The scope of work detailed in the main part of the Written Scheme of Investigation is aimed at meeting the aims of the project in a cost-effective manner. The Oxford Archaeological Unit attempts to foresee possible site-specific problems and resource these. However there may be unusual circumstances which have not been included in the costing and programme.

- Unavoidable delays due to extreme bad weather, vandalism, etc.
- Complex structures or objects, including those in waterlogged conditions, requiring specialist removal.
- Extensions to specified trenches or feature sample sizes requested by the archaeological curator.

## 23 HEALTH AND SAFETY AND INSURANCE

All work will be carried out to the requirements of *Health and Safety at Work, etc. Act 1974*, *The Management of Health and Safety Regulations 1992*, the OAU Health and Safety Policy, any main contractors requirements and all other relevant H and S regulations.

A copy of the OAU's Health and Safety Policy is supplied.

### 23.1 Disposal of materials

Coffin liquor, disposable paper suits and respiratory protection equipment are all classified as clinical waste and must be collected and incinerated by approved contractors. Lead can be stored and recycled. Rotting wood from coffins can be disposed of by agreement with the local waste regulation authority. The disposal of decontaminating fluids into sewers requires approval and possibly a license. All of the above will be the responsibility of the Enabling Contractor.

Lead coffins can weigh up to one third of a ton. It is proposed that the removal of these in undertaken by the Main Contractor through the use of specialised lifting equipment.

### 23.2 Insurance

The OAU holds Employers Liability Insurance, Public Liability Insurance and Professional Indemnity Insurance. Details will be supplied on request.

The OAU will not be liable to indemnify the client against any compensation or damages for or with respect to:

The use or occupation of land (which has been provided by the Client) by the Project or for the purposes of completing the Project (including consequent loss of crops) or interference whether

temporary or permanent with any right of way, light, air or water or other easement or quasi easement which are the unavoidable result of the Project in accordance with the Agreement;

Any other damage which is the unavoidable result of the Project in accordance with the Agreement;

Injuries or damage to persons or property resulting from any act or neglect or breach of statutory duty done or committed by the client or his agents, servants or their contractors (not being employed by the Oxford Archaeological Unit) or for or in respect of any claims demands proceedings damages costs charges and expenses in respect thereof or in relation thereto.

## 24 COPYRIGHT AND CONFIDENTIALITY

Oxford Archaeological Unit will retain full copyright of any commissioned reports, tender documents or other project documents, under the Copyright, Designs and Patents Act 1988 with all rights reserved; excepting that it will provide an exclusive licence to the client in all matters directly relating to the project as described in the Written Scheme of Investigation.

Oxford Archaeological Unit will assign copyright to the client upon written request but retains the right to be identified as the author of all project documentation and reports as defined in the Copyright, Designs and Patents Act 1988 (Chapter IV, s.79).

OAU will advise the client of any such materials supplied in the course of projects, which are not OAU's copyright.

OAU undertakes to respect all requirements for confidentiality about the client's proposals provided that these are clearly stated. It is expected that such conditions shall not unreasonably impede the satisfactory performance of the services required. OAU further undertake to keep confidential any conclusions about the likely implications of such proposals for the historic environment. It is expected that clients respect OAU's general ethical obligations not to suppress significant archaeological data for an unreasonable period.

MA Palaeopathology and Funerary Archaeology, Sheffield

PhD candidate (Neolithic and Bronze Age burial in the Upper Thames Valley), Institute of Archaeology, London

Member of the Osteoarchaeological Research Group, the Association for Environmental Archaeology, the Palaeopathology Association and the British Association of Biological Anthropology and Osteoarchaeology.

**Relevant experience/key qualifications**

Experienced in all aspects of post-excavation including the management and monitoring of projects. Produced and edited publication reports including a major two volume monograph. As an osteoarchaeologist, has prepared tenders for cemetery excavation and has written numerous reports and assessments on human skeletal remains. A skilled excavator of human remains and a lecturer and teacher of biological anthropology and burial practices from all periods. Written numerous small finds reports with a particular emphasis on Anglo-Saxon material.

**Experience****1990-present: Oxford Archaeological Unit**

Responsibilities include: management and monitoring of archaeological projects; preparation of project designs, assessment and analysis; production of publications and archives in accordance with English Heritage procedures; preparation of WSIs; training individuals in post-excavation skills; editing and proof reading.

Osteoarchaeologist: lecturer and teacher of biological anthropology and burial practices of all periods from the Neolithic to the 19th century. Produced numerous assessments and reports on cemeteries and human skeletal remains for publication. Provides specialist advice to various groups (human bone consultant to Thames Valley Police Force, Member of Archaeology Working Party for the Council for the Care of churches producing draft guidelines on the treatment of human remains). Cemetery excavation (prehistoric, Roman, Anglo-Saxon, medieval and post-medieval). Performs finds analysis, particularly for Anglo-Saxon small finds and post-medieval coffin fittings.

**Main areas of interest**

Osteoarchaeology. Palaeopathology. Prehistoric and post-medieval funerary practices. Cemetery excavation.

### Main projects

Recent main projects include the excavation of a Romano-British cemetery in Pepper Hill, Kent and editing and management of Reading Business Park post-excavation, a major late Bronze Age settlement. Numerous assessments of cemeteries and human remains, including Radley Barrow Hills, Berinsfield and Didcot cemeteries, Asthall Roman town, Butler's Field, Lechlade and St Nicholas Church, Sevenoaks, Kent. Recently completed editing of monograph on major excavations along the route of the A417/A419 Swindon to Gloucester road scheme.

### Main strengths

Post-excavation. Management. Human skeletal remains and cemetery excavation. Identification and analysis of various artefact categories. Romano-British and Anglo-Saxon small finds. Training skills. Teaching in Oxford University Department for Continuing Education.

### Academic Publications

Author of numerous publication reports on excavations, cemeteries of all periods and human remains. Presented numerous lectures on human skeletal remains, cemeteries and burial practice

---

**CURRICULUM VITAE {PRIVATE }****David Score****Site Supervisor**

{Updated: 22/11/99}

Date of birth 20/9/1963

Year joined firm 1996

Education/professional achievements

BA(Hons) Archaeology, Reading

**Relevant experience/key qualifications**

Considerable field experience from numerous archaeological projects, including complex urban and rural excavations covering a wide range of periods. Also experienced in staff and machine supervision, fieldwalking and post-excavation assessment and analysis.

**Experience****1996-present: Oxford Archaeological Unit**

Excavation duties on sites that include major urban excavations in the centre of Reading, the site of the Woolwich Arsenal in London, rural excavations in Kent for the Channel Tunnel Rail Link and a large excavation for the Maidenhead, Eton and Windsor Flood Alleviation Scheme. Also excavated human remains during excavations at St Augustine's Abbey in Canterbury and during an extensive cemetery excavation at St Bartholomew's Church, Penn, Wolverhampton. Performed watching briefs on the laying of pipelines for Thames Water and on the installation of a major gas pipeline along the coast at Great Yarmouth. Has recently monitored excavation of service cable trenches at Dorchester Abbey and improvement works at Buckingham Palace. Has also undertaken various fieldwalking projects including work on Salisbury Plain. Other responsibilities include assessing impacts of development, writing Written Schemes of Investigation and post-excavation assessment and analysis. This has involved liaison with specialists and clients, library research and writing reports to publication standard. Also presented lectures and given site tours to members of the public.

**Main areas of interest**

Particularly interested in presenting archaeology to the public. An active member of the Basingstoke Archaeological Society for whom DS has directed excavations on a late Iron Age/Romano-British enclosure. Work abroad has involved a research excavation in Ostia, Italy, and an excavation and survey of Epi-Palaeolithic sites in southern Jordan.

**Main projects**

Reading Oracle; White Horse Stone, Maidstone; Lots Hole, Dorney for the Maidenhead, Windsor and Eton Flood Alleviation Scheme; St Augustine's Abbey, Canterbury; Fulbourn Hospital, Cambridge; The Royal Arsenal, Woolwich, London; Dorchester Abbey, Oxon; Buckingham Palace, London. Previous projects include sites for the Southern Hebrides Mesolithic Project on Colonsay and Islay and excavation of a Neolithic chambered tomb in Inverness for Reading University.

**Main strengths**

Excavation and post-excavation skills include site photography and surveying; evaluations and test pitting; staff and machine supervision; finds and environmental processing; preparation of marketing and display material. DS often has to plan his work to coincide with the work programmes of major development projects and he is particularly accomplished at liaising and working with other contractors on site.

**Publications**

In addition to producing client reports for smaller projects, DS is author of the publication for excavations at Fulbourn Hospital, Cambridge.

**CURRICULUM VITAE {PRIVATE }****Adam Brossler****Site Supervisor**

{Dated 22 Nov 1999}

Date of birth 16/9/1971

Year joined firm 1997

Education/professional achievements

BA(Hons) Archaeology and Prehistory, Sheffield

**Relevant experience/key qualifications**

Field archaeology experience on deeply stratified urban sites and large-scale rural excavations. A variety of field techniques including field walking, test pitting, small and large scale evaluations and excavations, watching briefs, building surveys and recording, finds processing, post-excavation analysis, archive and cataloguing. An understanding of basic surveying principles and their application in the field. Experience of supervising sites with complex stratigraphy.

**Experience****1997-present: Oxford Archaeological Unit**

Supervisor: worked on a number of projects from deeply stratified urban excavations, such as Reading Oracle, to small-scale evaluations and watching briefs. Involved in excavation of Roman cemetery at Pepper Hill in Kent. Duties have included supervising areas of excavations, compiling various site matrices, of up to 4500 numbers, and checking site records. Also involved in the post-excavation process on a number of projects and has produced seven written client reports. Currently writing up the results of the Reading Business Park excavations for a monograph in addition to three other projects.

**1997: Trust for Wessex Archaeology and AOC (Archaeology) Ltd**

Site assistant: employed on a number of excavations and evaluations in Greater London, Essex and Kent for Wessex, which including some records checking. For AOC worked on a Roman to post-medieval site in Moorgate, London. General duties including responsibilities for the matrices and written record for small areas of the site. Single context recording.

**1996: A.C.R.E. and Dept. of Government Antiquities, Beirut, Lebanon**

Supervisor: excavation on a deeply stratified late antique to modern urban site (BEY 071). Duties included supervision of students, responsibility for the matrix and written record for an area of the site and building survey. Also supervisor of part of an excavation of a Roman/Byzantine bath house complex in Beirut. This was a deeply stratified urban site excavated using the single context planning method. Duties included building recording.

**1996: Oxford Archaeological Unit**

Field technician: took part in excavations for the A47/A419 Swindon to Gloucester Roadscheme and the Maidenhead, Windsor and Eton Flood Alleviation Scheme.

### **1995: Southern Albania and Italy for Prof R Hodges**

Archaeologist: varied role within a small team with duties based around the evaluation of sites and standing monuments in southern Albania and work on the San Vincenzo archive.

### **1994-1995: The British School at Rome**

Archaeologist: diverse roles and responsibilities based around the projects of San Vincenzo and Elba in Italy and Butrint, Albania. Duties included the supervision of areas relating to the different projects, responsibility for the written record, matrices and written reports. Other work included building survey, cataloguing and general archive work.

### **Main areas of interest**

Urban stratigraphy. Archaeology abroad. Post-medieval industrial archaeology. Bronze Age Britain.

### **Main projects**

Recent larger projects include: Watford Leavesden Aerodrome; Burghfield Moore's Farm; Shorncliffe Quarry; Reading Oracle; Maidenhead, Windsor and Eton Flood Alleviation Scheme and the A417/A419 Swindon to Gloucester Roadscheme. Previous projects include: excavations at Moorgate in London, at Leipzig, Germany, an excavation in the Czech Republic and sites in Beirut.

### **Main strengths**

Particularly skilled at understanding and describing stratigraphy. Experienced with both single and multi-context planning and recording systems on deeply stratified urban sites and large scale rural excavations respectively. Supervisory background and experience of excavating human skeletal remains and working independently on watching briefs. Computer and language skills.

### **Academic Publications**

Brossler, A, 1998 A survey of surface features at Fool's Venture Mine, Bonsall Leys, Derbyshire, *Mining History* (Bul. of the Peak District Mines Historical Soc.)13: 5, 65-71

Parker Pearson, M, Brossler, A and Rayles, A, 1999 Worked bone and antler, in *Between Land and Sea: Excavations at Dun Vullan, South Uist, Sheffield* (M Parker Pearson and N Sharples), 217-228, Sheffield Academic Press.

In preparation

Brossler, A, All Saints Church, High Wickham. In *Church Archaeology*.

Brossler, A and Boyle, A, Fonts of knowledge or just a load of old rubbish?. *TAG paper*

Brossler, A and Early, R, *Excavations of an early prehistoric landscape at Reading Business Park, Berkshire, Phase 2*. Thames Valley Landscapes Series.

Brossler, A, Gocher, M and Laws, G, Excavations of a late prehistoric landscape in the Upper Thames valley at Shorncliffe quarry. *Trans. Bristol Gloucestershire Archaeol. Soc.*

### **Lectures**

24/4/99 Reading Business Park: The results of phases 1 and 2. At Place and space in the British Bronze Age: An open forum for the presentation of research and excavation results, Cambridge University, Cambridge.

**CURRICULUM VITAE/PRIVATE }****Julie Anne Roberts****Osteologist**

Date of birth 25/06/66

Education/professional achievements

**BA (Hons.) Ancient History and Archaeology [2:1]**, University of Manchester**MSc. Osteology, Palaeopathology and Funerary Archaeology**, Dept. Prehistory &Archaeology, University of Sheffield, Dept. Archaeological Science, University of  
Bradford**ENB 219 Orthopaedic Nursing**, School of Nursing, Robert Jones and Agnes Hunt  
Orthopaedic Hospital, Shropshire**Relevant Experience/key qualifications**

Proficient in the osteological analysis of inhumed and cremated human remains. Experienced in techniques of archaeological fieldwork, including excavation, planning and survey. Ability to undertake quantitative analysis of large sets of data, when necessary using computer applications such as *Excel* and *SPSS*. Ability to work alone or as part of a multidisciplinary team. Good communication skills. Flexibility in terms of working conditions, schedules and travel.

**Experience**

Since the completion of undergraduate and postgraduate degrees in 1995, J Roberts has undertaken osteoarchaeological and forensic anthropological projects in Britain, Ireland, Turkey and Kosovo, for a large number of institutions (among others: The United Nations, Glasgow University Archaeological Research Division (GUARD), British Institute of Archaeology at Ankara and Dumbarton Oaks University, Washington DC etc)

As a qualified biological anthropologist and archaeologist she is experienced in the excavation and analysis of both inhumed and cremated human remains from archaeological sites of all periods. This work involves the examination of disarticulated and articulated bones in the ground, as well as their in depth study in laboratory conditions. She is able to determine the species of remains and, where preservation allows, sex and age at death. She is able to identify pathological conditions affecting the skeleton and to record metric and non metric data, with the purpose of creating demographic and epidemiological profiles of archaeological populations. In cremation burials JR has studied such factors as bone fragment size, colour, representation of skeletal elements and the minimum number of individuals per burial, with a view to interpreting and understanding mortuary practices. As a forensic anthropologist, she has undertaken work for various police forces in Scotland, and the United Nations. This work has involved establishing the identity of the deceased, providing information regarding cause and manner of death, and gathering and recording evidence.

## **Osteological Experience**

### **2000**

Exhumation and identification of war victims in Kosovo  
 Analysis of skeletal remains from Holy Loch Dunoon  
 Analysis of skeletal remains from Largs Bay  
 Analysis of Bronze Age cremated remains from Orkney  
 Analysis of skeletal remains (15-19th century) from Ennis Friary, Co. Clare

### **1999**

Analysis of cremated remains from crime scene, Port Glasgow  
 Exhumation and identification of war victims in Kosovo  
 Analysis of skeletal remains from Holy Loch, Dunoon  
 Survey of a First World War battlefield site in Libya  
 Co-production of policy document for the treatment of human remains in Irish archaeology  
 Excavation of skeletal remains from St Ninians Isle  
 Analysis of skeletons from a medieval cemetery in St. Andrews  
 Analysis of skeletons from a medieval cemetery in Dunbar  
 Analysis of Bronze Age cremated remains from Orkney

### **1998**

Analysis of skeletons from a medieval cemetery in Dundee  
 Assessment of skeletons from Tarbet Old Church, Portmahomack  
 Analysis of skeletons from Montrose,  
 Excavation and analysis of inhumed human remains from Crantit Neolithic Tomb, and cremated remains from cists within surrounding mound.  
 Excavation and on-site analysis of 18th and 19th skeletons from Ennis Friary, Co Clare  
 Analysis of cremation burials from Fordhouse Barrow, House of Dun, Couper Angus  
 Identification and reconstruction of burnt cranial fragments from two murder victims  
 Post-mortem examination of unidentified male, Loch Lomond

### **1997**

Excavation and analysis of Bronze Age cremated remains from Benderloch, Argyll  
 Analysis of medieval skeletal remains from Skaill House, Orkney  
 Excavation and recording of skeletal remains from Colonsay House, Colonsay  
 Analysis of prehistoric cremation burials from Fox Plantation, Stranraer  
 Analysis of skeletal remains from Byzantine rock tomb, Amorium, Turkey (phase 2)  
 Analysis of medieval skeletons from the Isle of May  
 Analysis of prehistoric cremation burials from Cloburn quarry, South Lanarkshire  
 Analysis of prehistoric cremation burials from Allenfearn, Invernesshire  
 Analysis of prehistoric cremation burials from Rhiconich Hut circle, Sutherland

### **1996**

Analysis of skeletal remains from Byzantine rock tomb, Amorium, Turkey (phase 1)  
 Analysis of animal bones from Skaill Bay, Orkney  
 In situ analysis of medieval skeletons, Skaill House, Orkney, and skeleton in cist, Skaill Bay  
 Analysis of medieval skeletons from Chapelhall, Inellan  
 Analysis of Prehistoric cremation burials, Kirkton, Fife  
 Analysis of cremation burials from Roman cemetery, Cross Farm, St. Albans

**1995**

Analysis of Neolithic skeleton from Llandudno, Wales

Post-excavation processing of cremation burials from Bronze Age barrow cemetery, Orkney

Analysis of Iron Age skeletal remains from County Mayo, Ireland

**1994**

Excavation of Bronze Age Barrow Cemetery, Orkney

**CURRICULUM VITAE (PRIVATE)**

Melanie Jane Richmond

**Archaeological Consultant**

Date of Birth 4/11/64

**Education/professional achievements**

1976-82 University of Glasgow

Master of Arts (Hons), in Archaeology, 1991

**Relevant experience/key qualifications**

Self-employed archaeological consultant working mainly with GUARD since 1990 on a variety of sites ranging in period from Neolithic to nineteenth century graveyards, employed as both project director and manager. Major projects include excavations at Glasgow Cathedral and Govan Old Parish Church.

Specialist employment includes examining, cataloguing and reporting on the coffin furniture recovered from the Quaker Burying Ground at Kingston-upon-Thames (for English Heritage); Glasgow Cathedral and Govan Old Parish Church (for GUARD).

Experienced in small finds work both on site and in post-excavation analysis with particular attention to early Victorian funerary artefacts. Expertise in database creation and general administrative duties. Photography skills including small finds work. Qualified First Aider.

**Experience**

1990-present: Archaeological consultant working mainly with GUARD

1991-1992: The Barnhouse Project; Post-excavation. database

1992: M74 Video ("Motorway to the Past"); Marketing  
The Isle of May; Set up

1992-1993: Paisley Abbey; Post-ex. Finds  
Glasgow Cathedral; Field work, Finds assistant

1993

Glasgow Cathedral; Specialist post-excavation.

Inveresk; Post-excavation. Finds

The Northumberland Coastline; Historical/cartographic research

Cleughside & Muirhead Burnt Mounds; Manager of Post-excavation.

Glasgow Cathedral; Field work, Director

M74 in Glasgow; Historical/cartographic research

The Isle of May; Post-excavation. Finds

1994

Lanemark, New Cumnock; Field work, Director  
The Kincardine Bridge; Historical/cartographic research  
Glasgow Cathedral; Field work, Director  
St. Nicholas Church; Field work, Finds assistant  
Govan Old Parish Church, Field work, Finds assistant  
Govan Old Parish Church, Specialist post-excavation.

1995

Academic Research  
Granttown-on-Spey; Field work, Finds assistant  
M74 Project Collation; Documentary Research

1996

Bloomeries; Field work  
Part-time Technical Support Staff (Grade D) for GUARD

## **PUBLICATIONS**

Archaeologia Victoriana: The Archaeology of the Victorian Funeral, The Loved Body's Corruption, J. Downes & T. Pollard (Eds), 1999.

Forthcoming: The Coffin Furniture from Glasgow Cathedral, The Antiquaries Journal.

The Coffin Furniture from The Quaker Burying Ground, Kingston-upon-Thames, Sussex Archaeological Collections.

The author/co-author of 2 technical reports produced by GUARD

**CURRICULUM VITAE{PRIVATE }****Jonathan Chandler****Research assistant: Consultancy**

{Updated: 3/9/99}

Date of birth 10/3/1967

Year joined firm 1997

Education/professional achievements

BA Degree in Archaeology and Ancient History, Manchester University

Postgraduate Diploma in Field Archaeology, Oxford University Dept. of Continuing Education

Postgraduate Management Diploma, CITE Associates, London

RSA/Cambridge CTEFLA

**Relevant experience/key qualifications**

Considerable documentary research and analysis experience, including map and air photographic interpretation. Produced desk based assessments and impact studies in advance of archaeological projects and development. Computer experience includes use of GIS, AutoCad, Adobe Illustrator, Adobe Photoshop, AERIAL rectification software and the creation of databases. Archaeological field experience includes an urban multi-period site in the centre of Reading and sites in London, Scotland and Israel.

**Experience****1997-present: Oxford Archaeological Unit**

1998 Research assistant (Supervisor grade from Jan 2000): responsible for writing archaeological desk based assessments, environmental assessments and impact assessments for urban and rural sites, including large-scale development proposals and development by Statutory Undertakers. Map regression exercises, field inspection and air photographic interpretation and digital plotting.

1997 Field technician: Excavation duties at the urban multi-period reading Oracle project and at the Romano-British cemetery excavation in Pepper Hill, Kent.

**1996-1997: Postgraduate Diploma full-time work placements**

Air Survey Unit, RCHM (England): air photographic interpretation and plotting, and use of MONARCH database; Archaeology Section of Hampshire County Council planing department: incorporating data into the SMR and using GIS; Archaeological Field Survey, RCHM (England) using EDM total station, plane table and graphic survey. Included the production of a field report and hachured plan; Trent and Peak Archaeological Trust, including excavation, post-excavation, and EDM survey, use of CAD and pottery research. Dissertation on Urban Archaeological Assessment. Attended RCHM week-long course on building recording.

**1992-1996: Global Village Language Centre, Taipei, Taiwan**

English Teacher: teaching adults English as a foreign language in Taiwan's largest school.

**1991 Oxfam London Office**

Fundraising and Campaign department team member: created media database for the London area and chief organiser of the annual sponsored walk.

**1989-1990: Museum of London**

Archaeologist: excavation duties including the supervision of volunteers. A variety of projects in London, including the Tudor palace at Lambeth and Medieval priory at Merton.

**1982-1985: Temporary archaeological employment**

A variety of archaeological projects as a volunteer and as a paid member of staff, including pottery analysis for Passmore Edwards Museum Archaeology Unit, excavations of a Mesolithic site, Iron Age settlement and Roman forts in Scotland and excavation of a Bronze Age palace in Israel.

**Main areas of interest**

Drawing; photography; independent travel; IT; research.

**Main projects**

Reading Oracle; Pepper Hill in Kent; numerous desk based assessments for sites in Avon, Berkshire, Buckinghamshire, Cambridgeshire, Dorset, Essex, Gloucestershire, Hampshire, Hertfordshire, Isle of Wight, Kent, Lincolnshire, London, Rutland, Staffordshire, Surrey, Sussex, Norfolk, Northamptonshire, Oxfordshire, Warwickshire and Yorkshire. Involved in Stansted Airport Cultural Heritage Audit for BAA and a study of Hampshire watermeadows for Hampshire County Council.

**Main strengths**

Documentary research and analysis, particularly with maps and aerial photographs and production of desk based assessments. Developed computer skills, including use of GIS, AutoCad, Adobe software, and databases. Drawing and illustration skills. Excavation, field survey and pottery research. Language and communication skills.

**Academic Publications**

Numerous desk based assessments for archaeological sites and impact studies in advance of major developments.

Education/professional achievements

BA Joint Hons, Ancient and Modern History 2:2 1983-88 Durham

Cert. Of Proficiency in Field (Oxford University Extra-Mural Dept) 1987-88

**Relevant experience/key qualifications**

Three years experience as project manager and computer officer with a major contracting archaeological organisation. Specialised in the design and construction of archaeological databases for both clients and internal use and managed the introduction and application of new technologies including CAD and GIS to enhance the level of service offered by organisation. Responsibilities included field projects involving liaison with construction and development contractors, archaeological sub-contractors and the direction of site staff. Two years experience of large scales post-excavation projects (over 13000 contexts) and a solid foundation of seven years fieldwork experience with a variety of archaeological unit in the late nineteen eighties and early nineties.

## **Experience**

### **November 1999-present: Oxford Archaeological Unit**

Information Systems Officer: development and support of IT systems and applications in co-operation with the IS Manager;

In charge of major project database. Putting in place recording systems for OAU fieldwork in general, for post-excavation, for archives management and management data. Direct involvement with individual projects as they need input. Major responsibility for appropriate IT-leaning projects etcetera.

### **May 1999-Nov 1999: SR Communications PLC**

#### **Programming Manager and previously Programmer**

Responsible for managing a marketing database on behalf of a blue-chip client. Additionally the post involved the manipulation, and the automation of the transmission of client's dataset to very fast laser printers.

### **Dec 1996-May 1999: Norfolk Archaeological Unit (NAU)**

#### *Project Officer.*

Designer and programme of the Norwich Urban Archaeological Database detailing the archaeology and history of Norwich for the Planning Department, Norwich City Council.

Designer and Programmer of the NAU main databases and CAD tools for excavation data capture and post excavation analysis.

*Project manager* for the expansion of the NAU computing facilities from ten isolated computers to a three-site wide area network including CAD and GIS facilities. Provided first line support, help and advice for all applications used by the NAU.

*Project manager* for the three-dimensional survey of the Norfolk Keel, a seventeen metre long clinker-built cargo boat built in the eighteenth century. As the only known survivor of its class, the work was funded by the Heritage Lottery Fund. The survey was undertaken using photogrammetry and an intensive CAD analysis giving plans, sections and nautical lines drawings of the vessel and its six hundred timbers and several thousand nails.

Salvaged old computerised survey data for the Institute of World Archaeology, University of East Anglia, and provided a CAD drawing as the basis for further survey work carried out in Spring 1999.

Contributed to the wider aims of the Norfolk Museums Service by writing a data translator for transmission of a NAU database to the Norfolk Museums Service MODES artefact and accessions database.

*Project Manager* for evaluation and excavation at Lacon's Brewery, Great Yarmouth for the John Harris Design Partnership. Involved the excavations of shored trenches through deeply stratified archaeological deposits.

Nov 1992--Dec 1996: Norfolk Archaeological Unit  
*Research Assistant.*

1986-1992: on contract go major archaeological units including the Central Excavations Unit, Oxford Archaeological Unit and the Trust for Wessex Archaeology

*Field Archaeologist*

Worked for two years in Germany (Landesdenkmalamt Baden-Wurttemberg) at the Neolithic lakeside village at Hornstaad, Lake Constance and in Swiss Archaeology (1989-1990) at Lausen, near Basel.

*Site supervisor* for the Avon county Archaeological Unit (1991); the Central Excavations unit (1987) and the Gloucester City Excavations (1986-7)

**Main strengths**

Microsoft Access 2.0 and Microsoft Access 97. Skills include the normalisation of data, data validation. VBS, Access Basic, the use of Data Access Objects, user interface design, data analysis and report design.

AutoCADr14, ArcView 3 and ArcCAD Geographic Information Systems, General installation and configuration of plotters, printers and computers. Provided first-line support for users of all software used by the NAU, including AutoCAD release 14, ArcView 3 and MSOffice, and administer the Novell NetWare 4.11 network. Wrote all internal applications used by the NAU in Word Basic, AutoLisp and Access Basic.

Some experience in Delphi 3 and 4.

<b>CURRICULUM VITAE{PRIVATE }</b>
-----------------------------------

<b>Mark Lacey</b>
-------------------

<b>Site Supervisor (Surveyor)</b>
-----------------------------------

{Updated: 10/04/2000}

Date of birth        5/5/1973

Year joined firm    1997

Education/professional achievements

1996 MA (dist) Scientific Methods in Archaeology, Bradford

1995 BSc (Hons) Sociology and Social Psychology, Bradford

**Relevant experience/key qualifications**

ML is an experienced excavator and has supervised various evaluations and excavations. He specialises in surveying, AutoCad and oversees the digital recording system of a variety of fieldwork projects. ML has also carried out a number of geophysical surveys in Yorkshire (both resistivity and magnetometer).

**Experience**

**1997-present: Oxford Archaeological Unit**

ML worked as an excavator, surveyor and supervisor on a variety of projects, including Roman settlements at Thurnham Villa and Westhawk Farm, both in Kent, and the deeply stratified medieval excavations at the Château de Mayenne, Pays de la Loire, France. ML's main current responsibilities include carrying out and supervising digital recording systems which involves the use of the relevant computer software necessary to download and process total station survey data, digitise site plans, produce computer-based illustrations, rectify photography, and create GIS models. ML has also carried out earthwork surveys, and produced digital terrain models, including a large part of Verulamium. ML has also undertaken human osteo-archaeological and palaeo-pathological work, historic landscape assessment, environmental processing and analysis, and archaeological desk-based assessment.

#### **1996-1997 Chester Archaeology Service**

Excavator at the Chester Cathedral site in the centre of the city.

#### **Main areas of interest**

Main archaeological interests are the Iron Age, Roman and Saxon periods of Britain. Currently in the second year of the two-year part time post-graduate diploma course in Professional Archaeology at the University of Oxford.

#### **Main projects**

Channel Tunnel Rail Link excavations in Kent, including Thurnham Roman Villa. Roman towns at Westhawk Farm, Ashford, and Verulamium,. Château de Mayenne, France.

#### **Main strengths**

Digital recording and surveying systems. Environmental processing and analysis.

#### **Reports**

ML has written reports for desk top assessments, evaluations, watching briefs and environmental analysis, in addition to contributions to the post-excavation analysis of large excavations.

### **CURRICULUM VITAE**

**Mark Steven Peters**

**Site Technician**

Date of birth 03/06/1970

Year joined firm 2000

Education/professional achievements

B.A (Hons) in Archaeology (Grade I), University of Reading

#### **Relevant experience/key qualifications**

Field archaeology experience in England and abroad. General excavation, recording and photography skills.

Reading University: Human Animal Bone practical osteology skeletal reconstruction and ageing and sexing paelaeopathology.

Basic Disease reconstruction.

3<sup>rd</sup> year course: Burial Archaeology course - osteology and palaeopathology as well as general archaeology and theory.

## Experience

**Field technician (OAU):** work include excavation, evaluations, planning.

Worked on various sites as a member of small and large teams.

Roma, Ostia Field Project: Insula I.4  
Sept 1998

Excavations in the garden of the garden of  
the House of Jove and Ganymede

Exton, Hampshire  
August 1998

Excavation of an Anglo Saxon cemetery

Fishbourne Roman Palace  
July & August 1997

Research Excavation of 1<sup>st</sup> century Roman  
Building (Year 3)

Fishbourne Roman Palace  
August 1996

Research Excavation of 1<sup>st</sup> century Roman  
Palace Building (Year 2)

Fishbourne Roman Palace  
July 1995

Research Excavation of 1<sup>st</sup> century Roman  
(Year 1 of a planned five-year programme)

1986-1996:

Career in Missile Technology working mainly for  
Defence Research Invincible Agency Road in  
Farnborough, Hants

## Strengths

Substantial knowledge of many packages and systems, including Windows, Microsoft Office, Harvard Graphics, MATHCAD, ORCAD, SPICE as well as basic knowledge of languages and programming, such as Assembler; BASIC; C and Turbo C.

**CURRICULUM VITAE{PRIVATE }****Richard Tyler****Historic Building Officer**

{Updated 15/9/99}

Date of birth 18/5/1964

Year joined firm 1989

Education/professional achievements

Certificate in Architectural History (Grade I: Distinction), Oxford University Dept. Continuing Education

**Relevant experience/key qualifications**

Extensive experience in the techniques of detailed survey and recording of standing buildings from small-scale vernacular buildings (both rural and urban) to larger scale projects including Kensington Palace and the Tower of London. Responsible for the building survey element of the Château of Mayenne project, France. Previous responsibility for small-scale excavation and evaluation projects including supervision of on-site work and preparation of reports for clients and for publication (contributor).

**Experience**

1989-present: Oxford Archaeological Unit

**1991-present Historic Buildings Officer**

Numerous projects (with fully illustrated reports) on building and site investigations. Over the past nine years, studies and investigations have been undertaken on a large number of sites covering a range of differing forms, functions and dates; from 12th-century Romanesque chapels, through medieval town houses and vernacular buildings, churches and post-medieval Royal Palaces, to 1930s cinemas. Surveys include work for the Historic Royal Palaces Agency (now HRP) at Kensington Palace State Apartments and the Tower of London, and for the National Trust at Osterley Park, Cliveden House and Boarstall Tower, Buckinghamshire. From November 1996 until July 1998, RT was part of an OAU team working on a 3 year programme of archaeological excavation, architectural recording and historical research at the 10<sup>th</sup>-century Château of Mayenne, Pays de la Loire, France. Overall responsibility was held for the building survey element of the project, including all on-site survey work, computer modelling and the preparation of the architectural analysis volume (text and illustrations) of the final 'DFS' archive report

Since returning to the UK, RT has been responsible for the analysis and full recording of a series of medieval and post-medieval farmhouses in Kent in advance of, and during dismantling for re-erection as part of the Channel Tunnel Rail Link project.

Recent work has also included archaeological monitoring of the extensive internal re-ordering of St Aldate's Church, Oxford, publication of which is currently in preparation.

**1989-1991 Field technician:** experience in all aspects of on-site excavation and recording on both large scale rural and smaller scale urban projects.

### **Main projects**

Château of Mayenne, Pays de la Loire, France.

Kensington Palace State Apartments and the Tower of London (for Historic Royal Palaces).

Osterley Park, Chastleton House and Boarstall Tower, Bucks (for the National Trust).

St Aldate's Church, Oxford.

### **Main strengths**

Fully conversant with a broad range of manual, photographic and digital building recording techniques. Historical research. Computer skills. Public relations, education (school parties / work experience supervision) and presentation experience. Medieval standing structures. Languages: French (working knowledge with sound archaeological vocabulary). Liaison with specialists; conservators, architects and engineers.

### **Academic Publications**

1996 (with Hey G): 'Late Roman Occupation' in Hey et al 'Iron Age and Roman Settlement at Old Shifford Farm, Standlake' *Oxoniensia*, LX, p.93 - 175. OAHS.

1996 (with Boyle A): 'Excavations and Observations during building work' in Rowley T and Steiner (eds.) *Cogges Manor Farm, Witney, Oxfordshire: The excavations from 1986-1994 and the historic building analysis*. Oxfordshire County Council.

1997 (with Bradley P and Parsons M) 'The excavation of two Barrows at Merton, Oxfordshire.' *Oxoniensia*, LXII, p.51 - 86. OAHS.

Illustrations for Munby JT and Steane JM 1996: 'Swalcliffe: a New College Barn' in the Fifteenth Century' *Oxoniensia*, LX, p.333 - 378. OAHS.

## **SPECIALIST SUB-CONTRACTORS**

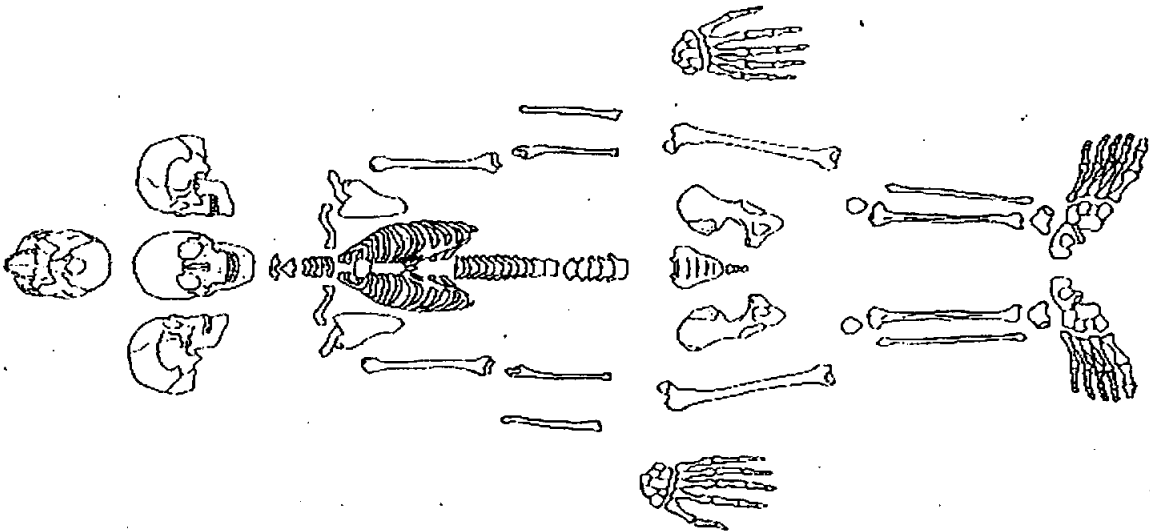

### **David Stevens: The Downland Partnership**

**The Downland Partnership** are an independent practice specialising in the precision recording of historic buildings, specifically through EDM survey, general and rectified photography, CAD modelling and digital image rectification. Customers include English Heritage, Historic Royal Palaces, The National Trust, D&C St Pauls Cathedral and D&C Westminster Abbey. A selection of the prestigious sites where work has been undertaken includes St Pauls Cathedral, Salisbury Cathedral, Windsor Castle, Kensington Palace and The Tower of London.

**David Stevens** is Co-Director of the Partnership and holds particular responsibility for photography, digital imaging and digital rectification. DS has worked in collaboration with OAU on numerous occasions, notably on the architectural recording of the Château de Mayenne, Pays de la Loire, France and most recently during extensive re-ordering works at St. Aldate's Church, Oxford.

Archaeological crypt clearance and recording

**OUTLINE RISK ASSESSMENT** - this outline risk assessment has been drawn up for the purposes of the OAU tender for the above project. If selected to carry out the work, OAU will expand this risk assessment and develop the Health and Safety Plan, Section Two (Necropolis, May 2000), to take account of OAU operations. OAU will fulfil the role of 'Contractor' as defined by the Construction (Design and Management) Regulations 1994.

CTA = Client To Advise

NB. FOR WORKS OF THIS KIND, PRIORITIES MUST BE CLEARLY ESTABLISHED. i.e. THERE MUST BE NO POTENTIAL FOR CONFUSION (LEADING TO POTENTIAL RISK-TAKING) BETWEEN THE FOLLOWING SITUATIONS:

1 WHERE STRUCTURES OR DEPOSITS ARE ARCHAEOLOGICALLY SIGNIFICANT, ADEQUATE TEMPORARY WORKS MUST BE CARRIED OUT TO ALLOW CORRECT LEVEL OF ARCHAEOLOGICAL RECORDING.

2 IF STRUCTURES/DEPOSITS NOT SUFFICIENTLY ARCHAEOLOGICALLY SIGNIFICANT, NO ACCESS FOR RECORDING.

PRIVATE LOCATIONS	HAZARDS	PRECAUTIONS/CONTROLS
All site	Vehicle access	Via existing roadways and to private land by agreement - access only to authorised persons - OAU trained minibus drivers only - banksman for all reversing
All site	Vehicle parking	Only in designated area(s) of site away from excavation operations
All site (external)	Roads and traffic	Exercise extreme caution. 'Hi-vi' safety vests to be worn when working near roads (e.g. surveying). Surveying staff and tripods not to be carried when extended.
All site	Vandals	Take all reasonable precautions to immobilise equipment and secure site, particularly site accommodation. 24-hour security on site, CTA
All site	Weather, dehydration, general health risks	Welfare arrangements to standard as set out in 2.9.2 Safety Plan
All site	Mechanical excavator strike or crush	Machine driver to be certificated as competent, and seen to be sufficiently skilled for safe archaeological work. Only designated, competent banksmen to work with and direct machine.
All site	Lifting equipment, strike or crush	OAU staff to keep clear of, and not to assist at such operations unless certification, competent, banksmen/slingers.
All site, particularly crypt	Unstable structures	No archaeological works until each area made safe, and certified safe by qualified engineer. Warning signs clearly displayed

PRIVATE LOCATIONS	HAZARDS	PRECAUTIONS/CONTROLS
All site	Strike, crush and noise from equipment.	<p>Daily inspection of equipment before work commences by trained person.</p> <p>Hard hats and Hi-Vi vests to be worn at all times.</p> <p>Protective footwear to be worn.</p> <p>Ear defenders to be worn if necessary.</p> <p>Hand tools - regular checks. Easily visible safety caps on all grid pegs.</p> <p>Guidelines for use of hand-tools - adequate space to work.</p>
All site	Contaminated land as defined in information provided by URL - landfill site and waste disposal site operated by Haul Waste. General risk (low) is wind-blown dust from waste disposal area. Specific risks, see below.	<p>Brief staff on nature and whereabouts of contamination. Masks available on site. (see also COSHH Statement)</p> <p>All staff to be made aware that they are working in close proximity to landfill sites operated by Haul Waste. All staff to be fully conversant with Haul Waste's "Health and Safety Statement for Contractors working with Haul Waste and Involving Work with Significant Health and Safety Hazards" attached as Appendix 2.</p>
All site	Falling (steps and deep excavations)	Solid barrier round all pits (double rail and footboard). Access to deep areas by fixed ladder only. Warning signs clearly displayed.
All site	Tripping/falling	Site to be kept tidy - all cables covered and secured. Adequate lighting to all areas.
All site	Services.	Services information from statutory authorities. Underground services marked out on site. CAT scan of all test pit positions before excavation. Contact statutory authorities if previously unknown services found. Initial excavation by hand only in areas of suspected or known services.
Scaffolded areas	Fall from or collapse of scaffolding	No access to scaffolding for OAU personnel without site manager's permission - scaffolding only to be accessed if inspected and safe (?Scafftags, CTA)
All excavations	Crush or strike from trench collapse	All excavations to be stepped or adequately supported. Shoring to be installed only by competent personnel.
All site	Strain injuries from manual handling, particularly in confined spaces	Manual handling assessment for all unusual lifts, and for each confined area. Lifting equipment to be used whenever possible. Lifting of barrows, buckets etc to use leg-bend, not back, with load close to body

{PRIVATE} LOCATIONS	HAZARDS	PRECAUTIONS/CONTROLS
Crypt and churchyard	Lead	Minimise dust. Monitoring of lead levels for all staff
<b>ZOONOTIC/BIOLOGICAL HAZARDS</b>		
All site	All zoonotic/biological	<p>All staff to wear rubberised gloves, overalls, rubber boots. Dampen dusty areas where possible.</p> <p>Appropriate face mask in dusty conditions, according to risk level - respiratory equipment to be last resort (i.e. is access for work really necessary).</p> <p>Good hygiene regime. Wash boots/gloves, remove PPE and wash face and hands (hot water and soap) before each break and at end of day. No smoking or eating on site except in designated areas. Antiseptic wipe to face before drinking on site.</p> <p>Health surveillance and testing for all staff based on advice from Dr S Young.</p>
All site	Weill's disease	Information to staff at induction, and issue of info. cards.
Areas soiled by birds	Ornithosis	Info. to staff at induction. Review and (if required) upgrade face mask specification
Crypt	Fungal spores/moulds	As above
All site	Tetanus	All staff to have up-to-date inoculations
Crypt	Anthrax	As ornithosis, + all soft tissue to be inspected when found by specialist for visible lesions. Specialist to advise if lesions found. Horse or other animal hair to be sampled and then sealed while sample is tested.
Crypt	Smallpox	As ornithosis, + all soft tissue to be inspected when found by specialist for visible lesions. Specialist to advise if lesions found.
All site	Stress	OAU are currently taking advice on this issue, with specific reference to long-term exposure to burials, and will develop a policy accordingly.

{PRIVATE } Version 1  
4th June 2000

## **ST LUKE'S CHURCH, OLD STREET, ISLINGTON, LONDON EC1**

### **OAU HEALTH AND SAFETY ARRANGEMENTS**

1. The OAU Health and Safety Policy is attached
2. OAU will act as contractor within the meaning of the word as defined by the Construction (Design and Management) Regulations 1994. As such, OAU will come under the safety management of the Principal Contractor.
3. OAU will draw up a detailed Health and Safety plan for their operations, which will develop the Health and Safety Plan (part two). The outline risk assessment (attached) will also be expanded as part of this exercise.
4. OAU staff will (subject to confirmation) be inducted by the Principal Contractor, but, notwithstanding this, OAU will draw up a list of site rules which summarise the Health and Safety Plan and Risk Assessment. Each new member of staff will receive a copy of this document and their attention will be drawn to the full safety documentation. At the time of receiving the document they will receive a verbal induction, explaining the document, with the opportunity to ask questions - this induction will be signed for and recorded. Inductions will be carried out by the Project Officer, Project Manager or Supervisor.
5. A weekly tool-box talk for all OAU staff will examine relevant safety issues, and provide an opportunity to raise concerns and discuss them.
6. OAU safety management on site will be the responsibility of the Project Officer, David Score, who will report to the Project Manager. The OAU Health and Safety Co-ordinator (David Wilkinson) will aid in the preparation of documentation and advise during the project.

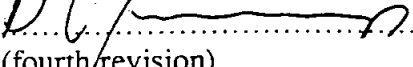

## OXFORD ARCHAEOLOGICAL UNIT SAFETY POLICY (Revision 4)

**Summary of Policy:** *The Oxford Archaeological Unit undertakes to safeguard, so far as is reasonably practicable, the health, safety and welfare of its staff and of others who may be affected by our work. This applies in particular to providing and maintaining suitable premises, ensuring the safety of all equipment supplied by the Unit and providing all reasonable safeguards and precautions against accidents.*

The responsibilities of staff, employees and volunteers in maintaining high standards of health and safety are set out below.

The policy will be reviewed from time to time as our activities develop.

Signed  Director and Chief Executive  
18/5/99 (fourth revision)

### STATEMENT OF SAFETY POLICY

- 1 The Safety Policy of the Oxford Archaeological Unit is, so far as is reasonably practicable:
  - i to maintain a working environment for employees which is, so far as is reasonably practicable, safe and without risks to health and adequate as regards facilities and arrangements for their welfare at work;
  - ii to provide and maintain plant and systems of work that are safe and without risk to health;
  - iii to make arrangements for ensuring safety and absence of risks to health in connection with the use, handling, storage and transport of articles and substances;
  - iv to provide such information, instruction, training and supervision as is considered necessary to ensure the health and safety of all staff, and to ensure that staff are competent to carry out their roles;
- 2 To achieve these four objectives, full co-operation between all staff is essential. While at work they will be expected to act with reasonable care for themselves, other employees and the general public.
- 3 A copy of this statement and any subsequent revision or amendment will be issued to all members of staff.

4 The Officer under whom the safety function is placed in the Unit is:

The Director and Chief Executive  
Oxford Archaeological Unit  
Janus House  
Osney Mead  
Oxford  
OX2 0ES

## SAFETY ORGANISATION OF THE OXFORD ARCHAEOLOGICAL UNIT

### *Company Safety Management Structure*

The **Director and Chief Executive** of the Oxford Archaeological Unit (OAU) is ultimately responsible under the terms of the Health and Safety Act (1974) for ensuring the safety of OAU employees. The director must: know the broad requirements of relevant legislation; attend meetings of their respective Health and Safety Committees; ensure that responsibility for health and safety is properly assigned and accepted at all levels. The Director and Chief Executive of the OAU is David Jennings.

The **OAU Safety Officer** represents the director on matters of health and safety; keeps abreast of relevant legislation and approved practice, and disseminates this information to OAU staff; advises staff as required on matters of health and safety; maintains the OAU health and safety records; calls and chair meetings of the OAU Health and Safety Committee; requests and receives consultation with/from staff Health and Safety Representatives. The Safety Officer of the OAU is David Wilkinson. The post of Safety Officer fulfils the requirement for a health and safety co-ordinator under the Management of Health and Safety at Work Regulations (1992).

The **Project Manager** is the person delegated to take overall charge of a particular project. She/he is responsible for health and safety matters on the projects which they manage, reporting to the Safety Officer in the first instance, and ultimately to the Director and Chief Executive. She/he must ensure that adequate safety arrangements, including an appropriate level of risk assessment, have been drawn up for the project, or for each phase of a project, and that these arrangements are implemented and maintained.

The **Site Director** is the person delegated to take charge of a particular phase of a project. She/he will be involved in drawing up the health and safety arrangements, and is responsible for implementing and maintaining the arrangements at project level. She/he is immediately responsible for the Health and Safety of employees under her/his supervision. She/he reports directly to the Project Manager.

The OAU Health and Safety Committee consists of the Director, Safety Officer, OAU Manager, Fieldwork Manager, the Site Staff Representative and two Health and Safety staff representatives. Meetings of the Committee are normally called by the Safety Officer when there is business for discussion, but may be called by other members of the committee. Project Directors or Project Managers may also be asked to attend, or may request to attend.

The OAU Health and Safety advisors provide professional advice on health and safety matters. They may advise the Health and Safety Officer, or directly advise a Project Director or Manager. They will audit OAU arrangements, including Health and Safety Plans. The OAU Health and Safety Advisors are Safety Services (UK) Ltd, Lakeside Industrial Estate, Stanton Harcourt, Oxford, OX8 1SL - 01865 883288.

### Individual responsibility

Each person working at an OAU site or premises is responsible for ensuring that their place of work is safe for themselves, their fellow workers and the public at large.

### OAU SAFETY MANUAL

The Unit has adopted the manual *Health and Safety in Field Archaeology* published by SCAUM (3rd Edition, 1997), and copies are available for consultation at the Units permanent offices. It also recommends the CBA *Safety in archaeological fieldwork* prepared by A. Olivier.

For further information on safe practices there are sets of copies of H&SE guidance notes which have been selected by our safety consultants as being of relevance to our work. These and other relevant information are held by the Safety Officer.

This information will be expanded from time to time by internal guidance memos on the safe use of equipment which is exclusive to the Unit.

06200

## Relevant legislation

The OAU will comply with all current and relevant Health and Safety legislation, including, but not limited to:

- The Health and Safety at Work etc. Act 1974
- Factories Act 1961
- Offices Shops and Railway Premises Act 1962
- Fire Precautions Act 1971

# **MINORIES PARTNERSHIP**

## **COMMERCIAL INSURANCE BROKERS**

150 Minorities, London EC3N 1LS. Telephone: 0171-264 2082 Fax: 0171-264 2097

### **CERTIFICATE OF INSURANCE**

The following is a summary of insurances prepared for Principals and others for whom our client is undertaking work.

This is a summary of the policies for quick and easy reference. If more detailed information is required please consult Minorities Partnership.

**The Insured:** Oxford Archaeological Unit

**Address:** Janus House, Osney Mead, Oxford OX2 0ES

**The Business:** Archaeological Services

\*\*\*\*\*

**Employers Liability Insurance**

**The Insurers:** CGU Insurance Plc

**Policy No:** 22267451 cci

**Period of Insurance:** From 30th June 1999 to 30th June 2000

**Limit of Indemnity:** £10,000,000 any one occurrence

**Extensions:** Indemnity to Principals  
Health and Safety at Work Act 1974

**Public/Products Liability Insurance**

**The Insurers:** CGU Insurance Plc

**Policy No:** 22267451 cci

**Period of Insurance:** From 30th June 1999 to 30th June 2000

**Limit of Indemnity:** Public Liability  
£5,000,000 any one occurrence, unlimited during the  
period of insurance

Products Liability  
£5,000,000 any one occurrence and in all during the  
period insurance

**Extensions:** Indemnity to Principals  
Cross Liabilities  
Health and Safety at Work Act 1974

**Professional Indemnity/Trustees Liability**

**The Insurers:** Lloyd's Underwriters

**Policy No:** NP049700U

**Period of Insurance:** 30th June 1999 to 30th June 2000

**Limit of Indemnity:** £2,000,000 any one claim and in all

**Contractors All Risks**

**The Insurers:** CGU Insurance Plc

**Policy No:** 22267478 CCR

**Period of Insurance:** 30th June 1999 to 30th June 2000

**Limit of Indemnity:** £1,000,000 any one contract site

**The Contract:** Any work carried out whether under the terms of a contract or otherwise and including speculative developments where appropriate

**The Cover:** The contract works, whether permanent or temporary, constructional tools and equipment and personal effects and tools belonging to employees

**Geographical Limits:** Anywhere in the United Kingdom/Europe

The Certificate prepared by:

## **Necropolis Method Statement for the removal of human remains (earth burial)**

### **1. Description of Work**

A photographic survey and narrative of site and memorials will be carried out for reference purposes prior to the commencement of any works

For documentation purposes, a 2m<sup>2</sup> grid plan will be made of the exhumation area to give an identity to both marked and unmarked grave spaces. This will enable a cross-reference between the exhumation and the reinterment locations to be fully documented for any future needs of any parties concerned.

Memorials will have been documented by archeologists and removed for storage off site prior to exhumation works commencing

Site reduction will commence by way of a strip-trenching method. This involves a mechanical excavator using a flat-edged ditching bucket to reduce a 2m wide trench in thin layers to allow disturbed grave infill to become visible. This process is continued down to coffin level or the exposure of skeletal remains.

At this stage the excavation will be made safe for removal of coffins and human remains by hand, or as conditions permit, removal by machine bucket to form spoil heaps through which exhumation operatives may carefully sort to remove human remains. This process will continue down to formation level. If remains are found to be buried below formation level, excavation and removal will continue until all remains are removed. The excavation will then be backfilled and compacted with approved fill material to formation level.

This process will take place from the outside edge of the exhumation area to a distance from the North wall of the church to be defined by Necropolis' structural engineer, once submitted to and agreed by the client's structural engineers. Once this agreed area has been cleared, the remainder will be similarly cleared in 2m wide trenches to the church wall, but trenches will only be dug in an agreed sequence, which will allow underpinning to take place in 1.2m lengths.

At all stages of excavation, agreed ground support systems will be employed as described per the attached drawings.

Each set of remains will be contained in an opaque plastic burial sack, which is tagged for identification / location, and removed to an approved storage facility prior to reburial. Six burial sacks will be placed in a single coffin, which will be used for the reinterment at Leatherhead cemetery. Any associated materials, such as lead linings and coffin timbers, will be treated with a phenolic disinfectant and reinterred with the exhumed remains.

Excavated material, once cleared of human remains will be removed from site by lorries for disposal as approved by the local Environmental Health Officer.

Plate 5.3 Diffuse idiopathic skeletal hyperostosis, skeleton 254

Plate 5.4 The skull of John Farmer, showing tumour or cyst

## Summary

Oxford Archaeology (formerly the Oxford Archaeological Unit) undertook an archaeological recording action at the Grade I listed St Luke's Church, Islington between July and December 2000 on behalf of ABL Cultural Consulting Limited. Oxford Archaeology was in attendance on Necropolis for the duration of the work. The work took place in advance of construction and refurbishment works in order to provide new educational and rehearsal facilities for the London Symphony Orchestra. The work comprised recording of funerary architecture, and the crypt structure along with exhumation of all burials in the northern and southern churchyards as well as clearance of all the burials in the crypt. A total of 1053 burials have been recorded and removed.

Osteological analysis on all the skeletal material was largely undertaken on site and completed in Oxford. The skeletal sample of 896 was divided into high and low resolution samples. The high resolution sample comprised 241 named individuals who were osteologically recorded in full. The remainder were unnamed individuals; for this group basic demographic information was recovered, stature was calculated where possible, a detailed dental record was compiled and pathology recorded where seen. Dental samples were recovered from the named individuals with the aim of refining microscopic ageing techniques.

A total of 712 coffins were recorded and removed for reburial. These comprised lead, wood, zinc and iron. A variety of coffin fittings have also been identified and recorded.

## Acknowledgements

The project was managed by Angela Boyle who was also responsible for the project design. David Score ran the work in the field. Janet Millar of WS Atkins was the archaeological consultant and Professor Margaret Cox was the academic advisor. The exhumation company was Necropolis and we would particularly like to thank Peter Mitchell, Tony McHale, Karen McHale and Roy Lander for their hard work and co-operation under what were often difficult circumstances. Osteological recording was carried out by Julie Roberts, Annsofie Witkin and Angela Boyle. Melanie Richmond recorded the coffin fittings. Much of the day to day site work was carried out by Andrew Norton, Darko Maricevic and Dan Sykes. Illustrations were produced by Ros Smith, Georgina Slater and Laura Kirby.

The work was carried out on behalf of Philippa Bird of ABL Consulting who Oxford Archaeology would like to thank for funding the project.

## CHAPTER ONE INTRODUCTION

*by Angela Boyle*

### **Location and topography**

St Luke's Church, Old Street (NGR TQ 32320 82423), is a Grade 1 listed 18th-century church which at the commencement of the Enabling Works was a disused, roofless structure. The walls of the nave, vestry and tower, which is attributed to Hawksmoor, survive (Plate 1.1). Beneath the church there is a crypt, with a number of vaults or bays containing coffined human remains. The church lies within its churchyard, set back from the busy east-west running Old Street, within the London Borough of Islington, in the parish of St Giles without Cripplegate. It is bounded by Helmet Row to the west, Ironmonger Row to the east, Old Street to the south and Mitchell Street to the north (Figure 1.1). The site lies on the Third Terrace above the river Thames. Where it has not been quarried away, the underlying natural substrate is brickearth, overlying Thames terrace gravels. The site is flat and the present-day ground level is *c* 20.5 m OD.

### **Archaeological and historical background**

The church is located at the extreme north-west limit of the 'Moorfields Marsh' which is known to have been landfilled in the early post-medieval period. Accounts made at the time of the construction of the church mention marshy conditions (MoLAS 1996, 20). St Luke's was constructed as part of the Commission for Fifty New Churches, which was set up in 1711; at this time the parish of St Giles Cripplegate was reported to have 4600 houses. The church was consecrated in 1733. Repairs to the structure of the church were undertaken in 1734, 1869, 1877, 1914 and 1951. The building has been prone to subsidence and cracks were visible in the north and south walls prior to commencement of the work. The church was built over a semi-subterranean crypt, constructed of brick as an integral part of the church structure. Although it was initially prohibited from use for burials the Vestry minutes first list fees for burial in the crypt in 1740 (see Chapter 2 below). There were known to be both earthen and

vaulted graves within the churchyard which had been landscaped. No headstones survived *in situ* but a small number of chest tombs remained. The chest tombs, railings and gate are listed Grade 2.

An archaeological watching brief was undertaken by MoLAS on five test pits excavated against the exterior walls of St Luke's in order to assess the composition and state of repair of the foundations to the church and the material in which they were constructed. It was not clear from the test pits whether the foundations to the church were constructed in a trench or whether the surrounding material was dumped later. No archaeological levels demonstrably earlier than the church were revealed. This investigation suggested that there were likely to be few inhumations in the immediate vicinity of the church. Inhumations were encountered in test pits 1 and 2, those in the former at a depth of only 0.8 m. Burial vaults were identified in test pits 2 and 3. In the northern churchyard burials were found to be at least 1.5 m beyond the north wall and 0.90 m from south wall in the south churchyard during OA investigations.

A desk-based assessment produced by MoLAS (1996) details all existing documentary sources. This was followed by an assessment of the archaeological potential of the site, particularly in relation to the study of post-medieval human remains, and the development of recommendations for archaeological mitigation (Cox 1997; 1998). A conservation plan for the site and building was prepared by Purcell, Millar and Tritton.

Palaeolithic and Mesolithic remains (450,000-4,000 BC) are found within the natural deposits of the area. The London region is an important area for finds of Palaeolithic implements which elsewhere in northern Europe have been removed by the action of successive Ice Ages. The distribution of such finds is more or less random and the chances of their occurrence on individual sites is very low; however, two Lower (earlier) Paleolithic flint hand axes have been recovered from within 400 m of the site.

Remains are rarely encountered in central London for the settled periods of prehistory (4,000 BC-AD 50); however a socketed wrought iron spearhead, considered to be Iron Age (700 BC-AD 50) was found at Golden Lane (c 200 m from the site).

The Roman city of Londinium was founded soon after the conquest of lowland Britain, c AD 50 and the area of the site is thereafter part of the hinterland of the largest and most complex urban settlement in Britain.

A large fort occupied the area of the city closest to the site in Roman times. It has been assumed to have been founded as a response to the sacking of the city in the native revolt of AD 60 and the recent identification of a tile of the British Fleet (Classis Britannia, inscribed CLBR), from excavations at 34 Noble Street, may indicate a continued military presence into the 3rd century but this by no means conclusive.

It has been suggested by Grimes (1968) that present day Old Street is a Roman road, part of an east-west communications line of which the existing road is only a small part. On the early maps Old Street does not appear as a continuous feature, but in spite of breaks in the Bethnal Green area it appears that to the east it made for the crossing of the river Lea at Old Ford. To the west the course of the road has various possible courses. Its present course in Clerkenwell and Farringdon is apparently quite a recent development. One 17th-century version by way of Long Acre, Kingsgate (the equivalent of the northern part of modern Kingsway), and Theobalds Road was used by King James I to by-pass the City on his way to his country seat at Theobalds, near Cheshunt. Another version of it appears to have joined Watling Street (modern day Oxford Street) to the north-west of St Giles-in-the-Fields.

The link with the Roman road has led to the identification of Old Street itself as a Roman road, though the fact that it ignores the city and may therefore have been in existence before the Roman occupation has been noted by Margary (1967). Old Street is often regarded as a branch of Oxford Street, on the assumption that together they may have formed a prehistoric route which was taken over by the Romans and developed a more southerly-branch along the line of Holborn with the foundation of London.

Grimes suggested that Old Street may have had a more important purpose in that it may have formed part of a link, located on the 50 ft gravel terrace between two important river crossings, at Old Ford and Putney.

Rodwell (1975), while trying to define the limits of London's town zone, suggested that the northern-boundary was the early road from Colchester to Silchester, believed to underlie Old Street.

Gravelled surfaces with stratified Roman coins were revealed in Victorian sewer excavations in Old Street during 1867. A vase and bronze armlets were found c 290 m and 340 m east of the site in 1912 and they may have been roadside grave goods. A coin of Nero was recovered in 1941. At Whitecross street, c 250 m to the south, a coin and gaming pieces were found and a residual sherd of samian pottery was found in a secondary (post-Roman) deposit on the Whitbread Brewery site (WTC76). These finds are scattered and would not have led to the build up of a stratified sequence of deposits as often occurs within the city walls.

### **Archaeological discoveries in the vicinity of the site**

A series of test pits were observed at 76-78 Old Street (OLD89) which showed post-medieval dumping and medieval stratigraphy overlying brickearth. The majority of the pits were too shallow to reveal the full extent and nature of archaeological survival on the site.

During excavation at 125 Golden Lane (GOL90) a block of dressed sandstone, pottery provisionally dated to the Tudor period and a post-medieval yellow glazed tile were found along with layers containing small greensand fragments.

Extensive areas of 17th-century brick quarrying were exposed during an archaeological evaluation at 198-208 Old Street. Large landfill deposits were found which included remains of industrial processes as well as domestic rubbish and building rubble. These deposits had been cut through by 18th-century features, including several walls and a well containing several whole wine bottles, porcelain and eastern influenced European tin glazed ware. These may be the remains of St Luke's workhouse. Structures of 19th-century date were also recorded.

At 122-128 Old Street (OLS94) an archaeological deposit was found along the east side of the site. It was interpreted as probable late 17th-century dumping, carried out as part of a large landfill event.

The probable boundary walls (BAH96) for the cemetery of St Luke's poor ground, known as the Pest House Ground, were recorded in an attempt to define the limits of the cemetery. A large quantity of disarticulated human bone was observed, probably from a charnel pit and articulated remains were seen in the trench sections.

## **Project background**

The St Luke's project involved the refurbishment of the Grade I church to provide rehearsal and educational facilities for the London Symphony Orchestra. Partial funding had been obtained from the Heritage Lottery Fund. The refurbishment work included the underpinning of the external walls, the provision of a new roof, conservation of the structure and the clearance of the crypt and part of the churchyard to accommodate the construction of additional space at basement level. It was predicted that the work would impact on the archaeological resource in three ways:

- Human remains needed to be removed from the crypt and graveyard
- Construction work in the graveyard and crypt was likely to disturb potential archaeological layers beneath the lowest burial levels
- The works would require disturbance to and the removal of some elements of the building structure, including the crypt.

As a result of the potential impact on the archaeological resource it became part of the planning condition that the Enabling Works must be archaeologically monitored. A Brief was produced by WS Atkins Heritage Consultants on behalf of St Luke's Centre Management Company and the job was put out to tender. Oxford Archaeology produced a Project Design in response to the Brief and was awarded the contract. The archaeological recording action took place between July and December 2000. OA were in attendance on Necropolis. Osteological recording continued at OA until February 2001 after which the remains were re-interred.

## **Academic objectives**

### ***Project Aims***

The main aim of this archaeological recording action was to record and interpret as much detail as possible within the parameters of a relatively rapid exhumation and reinterment exercise. It was believed that the archaeological data collected would contribute to the history and development of funeral trends and the demography of the population of the crypt and that part of the graveyard being disturbed. In addition, it

was anticipated that any data relating to taphonomy would be collected with a view to informing mitigation on future projects.

Specific objectives of the archaeological work included the recording of the preservation conditions within the crypt and churchyard, the inscriptions on coffin plates, and recording of the human remains and limited sampling of human skeletal remains with biographical data. The aims are detailed in chapter 6 where consideration is given to the degree to which they were achieved.

## **Archaeological methodology**

### ***Fieldwork Methodology***

All overburden and grave fills in the churchyard were removed to the uppermost levels of articulated remains (ie not including disturbed charnel) by the Enabling Contractor (Necropolis) under supervision of the Archaeological Contractor (OA). Where machining was not possible the Enabling Contractor was responsible for the hand-removal of the spoil and initial grave overburden. The Enabling Contractor was responsible for the removal of disarticulated remains from this spoil prior to its disposal. Removal of spoil within the crypt was also the responsibility of the Enabling Contractor.

A 10 m site grid covering the area of investigation was established. Within the churchyard a 5 m grid was deemed most appropriate. A temporary bench mark related to Ordnance Datum was created.

Excavation by Necropolis employed a grid system. Thus the churchyard was excavated in a series of 2 m<sup>2</sup> trenches, the spoil from each being used to infill the previous grid square, after it had been cleared of all charnel. As burials were revealed they were archaeologically recorded and removed.

### ***Recording system***

A single context recording system was not thought to be appropriate in this circumstance. Therefore, the focus of recording became the skeleton. Each interment was assigned a unique number from a continuous running sequence. The same number was assigned to the coffin and any associated fittings. This system had previously been applied successfully during the archaeological watching brief at St Bartholomew's, Penn, Wolverhampton which was carried out by OA in attendance

upon Necropolis (Boyle 2004). During this project 400 post-medieval burials were removed over an eight-week period.

All other contexts, ie vaults, brick-shaft graves and soil layers within the graveyard were assigned an individual context number. Preservation and completeness of skeletons was recorded *in situ* prior to osteological analysis on a scale of 1-4. Specialised recording forms were available for the recording of both coffins and skeletons. Charnel and disarticulated remains were not recorded although they were carefully cleared from all spoil prior to its disposal by the Enabling Contractor. Written descriptions were recorded on proforma sheets comprising factual data and interpretative elements.

#### *Plans*

Measured plans of the churchyard and the crypt were produced at a scale of 1:50 and all burials were located on these. Individual skeletons and coffins were not planned; provision was made for photographic recording as deemed appropriate. A register of plans was kept.

#### *Sampling strategies*

Soil samples for pedological analysis were taken during works within the churchyard in order to characterise the nature of the burial environment.

#### *Coffins and coffin fittings*

Wooden and lead coffins and any associated fittings, including nails, were recorded on the coffin recording sheet. All surviving coffin fittings were recorded in detail by reference to the published corpus of material from Christ Church, Spitalfields (Reeve and Adams 1993) as well as the unpublished catalogue of material from St Nicholas, Sevenoaks (Boyle 1995) and St Bartholomew's, Penn (Boyle 2004). Where individual types could not be paralleled they were drawn or photographed as appropriate. Condition of coffins and their associated fittings was recorded on a scale of 1-4. In addition there are detailed coffin recording sheets with supporting illustrative and photographic records.

#### *Photographic policy*

A black and white and colour (35 mm transparency) photographic record was maintained. The photographic record also included working shots to illustrate more generally the nature of the archaeological work. A colour slide lecture set has been compiled. A photographic record of the chest tombs was made prior to their removal (see Chapter 3). Photographs were recorded on OA Photographic Record Sheets.

Large and medium format photography was carried out by The Downland Partnership. They have been supplied to OA as high resolution TIF images on CD-ROM.

### ***Osteological methodology***

#### ***Low-resolution recording***

Skeletons which could not be identified were subjected to low-resolution recording. This includes a skeletal and dental inventory, age and sex assessments, gross pathological observations, and basic metrical recording for use in the determination of stature and sex. The aim was to provide enough information to reconstruct the demography of the skeletal assemblage.

#### ***High-resolution recording***

Named individuals and those of intrinsic osteological interest were recorded in more detail. The latter can be defined as those with unusual pathology, evidence of surgical or dental intervention and exceptionally good preservation. This level of recording entailed the addition of detailed descriptions of pathology and differential diagnosis, additional metrical recording, and a study of non-metric traits.

### **Health and safety**

At the time of the archaeological works the London Diocesan Fund held the freehold for St Luke's Church and the surrounding burial ground. As the church was then redundant, the exhumations did not require a Faculty. Rather, section 65 of the Pastoral Measure applied. For reasons of decency and dignity, the Church Diocesan Fund stipulated that sealed coffins should not be opened and that such coffins should be sleeved on site and removed for reburial. This stipulation was complied with at all times.

Home Office directions are required for the removal of buried human remains. A Home Office order was granted for the exhumations at St Luke's Church. The Home Office order relating to the exhumation works (dated 21 January 1999) stipulated that the removal shall be subject to agreement with the Chief Environmental Scientist for the London Borough of Islington.

OA had to demonstrate that they had planned a safe working practice by providing the Planning Supervisor and Principal Contractor with a Risk Assessment

and developed Health and Safety plan of all work to be done by the archaeological team, a current Health and Safety policy and the detailed specification for the archaeological watching brief.

The Health and Safety at Work Act 1974, under which the Personal Protective Equipment at Work Regulations are made, was complied with at all times by OA.

Funerary archaeology presents a specific and complex range of hazards. The risk of anyone contracting smallpox is remote but the potential threat to the population at large is such that it must be taken seriously. All staff wore protective clothing at all times.

Where wood coffins were used there may be an increased risk of infection due to occasional good preservation of bodies and other materials. The highest risk category is that of the sealed lead coffins. If any soft tissue remained the hazard presented was treated as potentially severe and suitable protective systems were used. It is not only the human remains themselves that present a risk but also the coffin linings and pads, and the result of the body's decomposition, a viscous black liquid. The greatest potential risk presented by this activity is that of contracting anthrax or smallpox. The risk for the archaeologist associated with working with the remains of a recorded anthrax death are thought to be small. A higher risk is gained from the well-preserved horse hair or woollen materials used in the coffin pads, pillows and packing. Minimum precautions are to wear the correct level of protective equipment. Shower facilities were provided by Necropolis.

There is a possibility of increased lead levels in blood due to the concentration of lead in the atmosphere. Constant monitoring of the health of the workforce was required for the duration of the work. A slight increase which was still within acceptable limits, was observed in all staff.

Strict adherence to the site Health and Safety policy produced by Necropolis was observed at all times. Personal protective clothing worn on site was not be worn outside the compound area. Mess, sanitary and washing facilities were provided by Necropolis.

All work was carried out to the requirements of *Health and Safety at Work, etc. Act 1974, The Management of Health and Safety Regulations. 1992*, the OA Health and Safety Policy, any main contractors requirements and all other relevant H and S regulations.

Coffin liquor, disposable paper suits and respiratory protection equipment are all classified as clinical waste and must be collected and incinerated by approved contractors. Lead can be stored and recycled. Rotting wood from coffins can be disposed of by agreement with the local waste regulation authority. The disposal of decontaminating fluids into sewers requires approval and possibly a license. All of the above was the responsibility of Necropolis.

Lead coffins can weigh up to one third of a ton. Their removal was undertaken by Necropolis.

### **Structure of the report**

Chapter 2 is a consideration of the documentary sources relating to the church itself such as Vestry Minutes and Faculties as well as parish registers (birth, marriage and death). It is not an exhaustive account. Chapter 3 describes the archaeology of the church and the graveyard while Chapter 4 looks in detail at coffins and their fittings; Chapter 5 considers the skeletal assemblage. Finally, Chapter 6 presents some overall conclusions about the data and evaluates the success of the particular methodological approach applied at St Luke's, particularly in relation to the reburial debate. Appendix 1 is a detailed catalogue of all the skeletons, coffins, fittings and vaults that were excavated and recorded.

## CHAPTER 2: THE DOCUMENTED HISTORY OF THE PARISH AND THE BURIAL GROUND

*by Angela Boyle*

### Archaeological and historical background

There are no historical records or archaeological finds which throw light on the area in the early medieval period. Finsbury was a manor in later medieval times and has been given a Saxon origin by some scholars (the *burh*, or fortified residence, of the family, *Finnes*); however, it is likely that it was a later medieval creation by subdivision. There is certainly no extant early charter, and its name may be derived from fen, describing the local topography of the Moorfield to the south-east. To the south-west of the site lay a signal tower called the Barbican, and later a house built on the spot is called Base Court. It is likely that this is a Saxon foundation that is cognate with Bassishaw (*Basingahaga*) a parish, ward and probable Saxon estate in the same fashion as the parish of St Mary Staining has its origin in the estate of the manor of Staines (*Staingahaga*).

When the Domesday Book was compiled the nearest manor mentioned was that of Hoxton and at that time this manor, together with Islington, the liberty of Bishopsgate and the Manor of Stepney belonged to the Canons of St Paul's Cathedral. The later manor of Finsbury was also part of their estate. The large area they controlled (most of the modern boroughs of Tower Hamlets, Hackney and large parts of Islington) reflecting the political necessity for areas near the city to be in the hands of Norman placemen: the bishop and other Diocesan appointments.

The area around the city was largely taken up with varieties of market gardening or dairy pasture. A later medieval tenement in Golden Lane had the name of *Le Mykelvine* (the Much Vine). The area of the ridge, to the east of the site, became built up as a suburb of the city. Whitecross Street is first recorded as *Everardes Wellestrata* in 1253, although then it may only have run as far north as Chiswell Street. It is recorded as *Wytecroychstrate* in 1285. The Abbot of Ramsey maintained an Inn, or large townhouse, on the corner of Whitecross Street and Beech Street. To the east of the site lay the three open fields of Finsbury manor (Mallow, Finsbury and Bunhill).

By the 15th century the land was owned by the Knights of St John. This can be seen from a transcript of St John Cartulary, the original document held at the Museum of the Order of St John of Jerusalem, Clerkenwell (Baildon Translation of Cotton MS Nero VI).

- *The Prior's charter of a vacant parcel of land in Old Street.*

*Indenture by which Brother Walter Grendon, Prior of the Hospital, lets to farm to William Russell, citizen and fishmonger of London, a vacant parcel of land lying in Old Street, Co Middlesex, in breadth between the land of the said prebend on the north and the highway on the south; from Christmas next for 60 years at a rent of 3s 4d with power of distress, and of re-entry if no sufficient distress can be found. Dated at Clerkenwell (Date not filled in, Grendon was Prior 1400-1416).*

- *The Hospital charter of seven gardens and two cottages built in Old Street.*

*Indenture by which Prior Robert Mallory lets to farm to John Grene seven gardens lying together with two cottages built upon them, between the lane leading to Wallokkesberne on the east, the high street called Old Street on the south, the highway leading to Islington on the west, and land of Thomas Frowyke on the north and east, with the issues and profits of the courtyard to the same gardens and cottages belonging; for 4-score years from the Nativity of St John the Baptist last (1439) at a rent of 33s 4d. The tenants to keep the premises in repair, as to the fences, hedges, ditches etc and to discharge all burdens and services due thereon; with power of distress; and of re-entry if rent is in arrears for 3 months or the premise in disrepair. Given at our house of Clerkenwell at the celebration of our Chapter there, Tuesday 30 June 17 Henry VI.*

There is a reference for the site in the Greater London Sites and Monuments Record as being the possible location of a medieval manor house, recorded as St Luke's Manor House. There is no other reference to this and it must be considered suspect, as most of the land in the area was owned by the Knights of St John, while the parish name of St Luke's only appears after the foundation of the church in 1711. The reference may originally have been derived from Aga's map of 1560 which shows buildings on the site.

In Tudor times the area around the site was still largely open and most likely used for horticultural purposes. The Drapers company built almshouses north of Beech Street and Richard Gallard founded some on Golden Lane, which continued a medieval tradition of almshouses and hospitals on the city fringes that continued well into the post-medieval period. Stow in his Survey of London, first published in 1598, describes Old Street thus:

*'...the way stretcheth up towards Isledon and on the right hand, or East side, at a Red Crosse turneth into Ealdstreete, so called, for that it was the old highway from Aldersgate Streete for the Northeast parts of England before Bishopsgate was builded, which street runneth East to a Smithes Forge, sometimes a Crosse before Shoreditch Church, from whence the passengers and Carriages were to turne North to Kings land, Tottenham, Waltham, Ware, &c.'*

The most obvious archaeological deposit associated with the beginning of the post-medieval period is a large landfill dump to the north of the City. Often referred to as the filling of the Moorfields marsh it is clear now that it far exceeded the boundaries of the marsh itself. The deposits were formed mostly of a mixture of nightsoil<sup>1</sup> and demolition debris and at Whitbread's brewery were 0.03 m thick. Under waterlogged conditions sometimes leather waste is also recovered and occasionally important industrial material is found. At Old Broad Street crucible fragments were recovered from Mansell's monopoly *Cristallo* glassworks; a factory which employed a free, international workforce, drawing on the most advance glassmaking techniques of the Muranesi glasshouses and decorative skills from the Netherlands.

In part this deposit represents a growth in the productive resources of the city as it often fills brickearth quarries used to rebuild London in brick; quarries which are not always recognized by the archaeological record as their sides often exceed the areas examined by archaeologists. Also the increased use of coal as a fuel meant that nightsoil was less useful as an agricultural fertiliser. The increase of the City's population at this time, as guild restrictions eased and the closure of the monasteries gave space to expand, may have overburdened traditional means of disposal.

---

<sup>1</sup> Excrementitious matter taken from cesspools etc at night.

## **The Commission for Fifty Churches**

St Luke's was constructed as part of the Commission for Fifty New Churches, which was set up in 1711, to alleviate the lack of places of worship caused by the Great Fire and exacerbated by rapid population growth at the time. The committee calculated that an additional 72 churches were required, although this was rounded down to 50 only 12 of which were actually built. Other well known examples include Christ Church, Spitalfields (begun 1723) (Reeve and Adams 1993, 3), St Anne Limehouse (1712), St George-in-the-East (begun 1715) and St George, Bloomsbury (begun 1716).

In response to the growing needs of that part of the town, St Luke's was taken out of the parish of St Giles Cripplegate. In 1711 St Giles Cripplegate was reported to have 4600 houses. The area which was used to form the parish of St Luke's was known as The Lordship. The parish of St Luke's is shown in Figure 2.1.

The land upon which the church was built was purchased from the Ironmongers' Company for the sum of £900, although it is clear from the minute books of the Commission that the construction process was a lengthy one.

### **The building of the church**

The architect of the church is traditionally disputed; the body of the church may have been built by John James, while the west tower, spire and flanking staircase are attributed to Nicholas Hawksmoor. The design has often been wrongly attributed to George Dance the Elder, a member of the Vestry who was buried there in 1768. His children commemorated him with a black marble slab 20 years after his death which has since gone.

The church was consecrated on the festival of St Luke, 1733, by Dr Hare, Dean of St Paul's and Bishop of Chichester.

### ***The Minute Books of the Commissions for Fifty New Churches (1711-27)***

#### ***Minutes of the Commissioners***

##### **5th December 1711**

Mr Williams offered a site for a church etc called the Mermaid Brewhouse in White Cross Street in St Giles Cripplegate at £550.

*Minutes of the Building Committee*

24th September 1712

Skeat delivered Ironmongers' Company's proposal for church near Old Street, Cripplegate.

Mr Wren and Mr Marlowe desired to view sites belonging to...Ironmongers' Company in St Giles Cripplegate and report.

30th March 1713

Agree to Ironmongers' Company proposal of 23<sup>rd</sup> March for site in St Giles Cripplegate, providing Company consent to build street leading thereto from Old Street before 25th March next. Otherwise, agree to proposal of 24th September last.

*Minutes of the Commissioners*

10th August 1716

Agree to give Ironmongers' Company £900 for their site in St Giles Cripplegate parish.

25th July 1717

A debate arising upon the fifth article of the Ironmongers' Company's proposals, resolved that no houses should be nearer than 25ft to churchyard wall, and no buildings nearer than 10ft.

12th September 1717

James to bring designs of a church for the Ironmongers' Company site in St Giles Cripplegate parish by next meeting; masonry between the compartments of windows to be range work of rag stone; Surveyors (Hawksmoor and James) to call on masons employed in churches to give estimates for rag stone.

10th October 1717

James submitted design of church for Ironmongers' Company site, St Giles Cripplegate. The said plan approved, James to bring two estimates to next meeting; one built with ashlar, the other with rag stone.

28th November 1717

Notice to be given in Saturday's Gazette for bricklayers' proposals for new church in Old Street 'with the best hard burnt bricks, free from sammel or 'under burnt bricks'.

23rd January 1717/18

Notice to be given in Gazette for receiving bricklayers and brickmakers' proposals for Old Street church this day fortnight.

13th February 1717/18

Surveyors reported on brickmakers proposals; referred to next meeting. Wilson, as the most reasonable of the bricklayers' proposals, appointed for Old Street church.

20th February 1717/18

John and Thos. Waxham to make good, hard, well-burnt bricks for Old Street church.

27th February 1717/18

Notice to be given in Gazette for proposals for digging foundations of Old Street church by this day fortnight.

13th March 1717/18

Form of contract with workmen for Old Street church to be considered at next meeting.

19th February 1718/19

Petition of James Wilson about one of the houses to be demolished on Ironmongers Company site to be complied with.

12th March 1718/19

On Dr Bennet's request, Surveyors to give orders for clearing ground in order to begin work on church in Old Street. James to prepare a plan and estimate for building in brick.

25th March 1720

Surveyors to estimate charge of fencing site in Old Street; Skeat to consult Wilson about preventing soil being laid there in future. Hawksmoor reported that the ground in Cripplegate (Old Street) purchased of Ironmongers Company is large enough for erecting a tabernacle without obstructing building a church on another part of it when Board is enabled to do so.

17th April 1721

Agent submitted proposals for parts of ground in Old Street from Jas Wilson, bricklayer and John Wilson. Wilson to be allowed the ground upon which a church is intended to be built, to be cleared and given up at 3 months notice

3rd May 1721

John Wilson attending, the Board refused to let him the ground in Old Street upon which a church is intended to be built unless he consented not to raise it above present level, with which he would not comply.

20th March 1723/4

Solicitor to have fresh directions to prosecute any who lay dirt or rubbish on site purchased in Old Street.

15th May 1724

Bennet reported that, having acquainted vestry of St Giles Cripplegate that he had delivered to Commissioners the vestry's agreement to convey to them Bear and Ragged Staff Yard provided they would allow parishioners to bury in the ground in Old Street, and that Commissioners had answered that they were willing, as soon as conveyance was made to divide the parish and give parishioners of Old Street church district free leave to bury there, vestry unanimously acquiesced.

23rd June 1727

A plan for a new church to be erected in parish of St Olave, Southwark was laid before Board, and another plan of a church to be built in Old Street in parish of St Giles Cripplegate, both approved. Surveyors ordered to direct workmen to begin digging foundations without loss of time.

24th July 1727

Goff's proposals for smith's at Old Street church approved; Solicitor to prepare contract. Advertisement ordered for mason's proposals for Old Street church.

4th August 1727

Mason's proposals for Old Street church referred to Surveyors.

25th August 1727

Surveyors having examined mason's proposals for Old Street church, Thos Shepherd to be employed.

11th September 1727

Solicitor to prepare contract with Jas Wilson and Benj. Prosser, bricklayers for Old Street Church.

22nd September 1727

John Beven to be employed as watchman, Old Street church.

27th October 1727

Read petition from Wilson, now in prison, praying he may be permitted to go on with brickwork of Old Street church. Surveyors to learn what proposals he will offer about finding security for his performance.

10th November 1727

De la Motte, an assignee of estate of Jas Wilson, bricklayer, a bankrupt, declared on behalf of creditors that he had no objection to Commissioners discharging Wilson from his contract and agreeing with another.

Hawksmoor and James having some time ago complained to Wilson of his not setting about bricklayers work at Old Street church, and he promising to set about it and to bring good security to Board this day for performing the contract, or he would be content to waive it, and Wilson not having begun it, or brought any security, and being a bankrupt and prisoner in Ludgate for upwards of a year, Commissioners judged that he ought not to be employed at Old Street church.

Benj. Prosser and Wm Cooper, bricklayers, proposing to do the work on the terms in Wilson's contract, proposal accepted. Solicitor to prepare contract.

The church was consecrated on the festival of St Luke 1733 by Dr Hare, Dean of St Paul's and Bishop of Chichester, and seems to have started subsiding soon after completion. The first account of repairs dates from 1734, with further attempts in 1869, 1877, 1914 and 1951. The church suffered some war damage in the 1940s but it is thought that the dry summer of 1956, combined with the effect of heavy bombing on nearby sites, caused more recent movement. In 1959 the roof was removed which not surprisingly, has had a disastrous effect on the rest of the structure. At the commencement of archaeological works the church was currently a 'ruin' with the subsidence evident on the north and east walls.

The following extract from *London Churches Ancient and Modern* by T. Francis Bumpus, (1908) describes the church prior to its virtual destruction:

*Externally it is a plain substantial stone structure, devoid, however of a sanctuary, with a western tower, rising properly from the ground, and surmounted by a fluted obelisk of graceful outline. On either side of the tower are square erections roofed with lead domes and containing the staircases to the galleries.*

*Within, St Luke's is dignified and imposing, and divided into a nave and aisles by lofty colonnades of the Ionic Order. The roof over the nave is semi-circular, as are those of the aisles which are vaulted transversely, in as many compartments as there are arcades, from the tall Ionic columns to consoles in the walls. The stonework is*

*painted white, and the details of the columns, etc are picked out in gold with pleasing effect.*

*Rich stained glass - mostly by Messers Heaton and Butler - fills the double series of windows on either side, the same artists being responsible for the very beautiful paintings in the three square panels of the altarpiece which has been profusely covered with gold. The glass in the east window, composed of a round headed centre and square wings, was inserted sixty years ago by Clutterbuck. The subjects the Nativity, Crucifixion and Ascension, are treated in the Cinquecento Flemish style, and much of the colouring is rich and fine.*

*Unfortunately by some blunder in taking the dimensions of the window, the central picture was painted much too large for its place, and it had to be cut down through figures in every direction. The group, which has caught all the coarse literal fidelity of the Cinquecento School is confused, there is an almost total absence of symbolic allusion, and of the devotional effect there is not a trace.*

*There are galleries on the north, south and west sides, and in the latter which is supported on Ionic columns, is the organ, a large plain instrument, presented to the church by a brewer of Old Street, named Buckley. Built in 1734, this organ in St Luke's is ascribed by some to Bridge, by others to Jordan, and it is said to be the first church organ to which the tremulant was applied. The swell, dub and super octaves were probably the earliest made in England.*

*This organ in St Luke's has some interesting associations. The Churchwardens of St Luke's had a property left them by the Ironmongers Company for church purposes, which grew into so large a sum that they did not know what to do with it. After much discussion it was decided that it should be spent on enlarging and improving the organ, the work to be done by Messers Gray and Davison. Davison was an old friend of the distinguished English church composer, Henry Smart, who at that time (1843 or thereabouts) greatly wished to have the use of a large organ, and thus it was not long after the giving of the order, Henry Smart heard of the fine instrument that was being built in St Luke's, Old Street, and the churchwardens received an application from him for the post of organist.*

*It should be mentioned that the then organist of St Luke's was blind, had given much dissatisfaction, and was deemed unfit to manipulate the new organ properly. Henry Smart was then a well-known man, and when he told the churchwardens that his chief object was to secure the use of a fine organ, and that he would, therefore,*

*come for £50 per annum, they accepted his offer, and also agreed to his one stipulation, that sufficient money should be allowed him to pay a professional quartet in his choir. He held the post of organist from 1844 to 1864.*

The organ case and font are now in St Giles without Cripplegate, with which the parish of St Luke's was reunited in 1959. A list of 1759 shows the plate weighed in ounces, drachms and grammes; the curtains and curtain rods were counted; and objects in the vestry room were enumerated: 'an umbrella, a table of fees, an Almanack, 8 Pewter Dishes, a knife to cut the sacrament bread, 2 Ink Stands, and a Chamber Pott.' Building alterations were carried out in 1877-78 by Sir Arthur Blomfield, when the east end was chancelled up a little and the reading desk removed. Until the 1930s two small domes surmounted the flat roofs on either side of the tower.

The building is Grade I listed (status ref. 635-1/75/6, dated 29/12/1950; area ref CA/1003/15); the railings and gate are Grade II listed (ref. 635-1/75/6, dated 29/9/1972). The Caslon family tomb in St Luke's Churchyard is listed Grade 2 (ref. 635-1/75/1, dated 28/9/1995). This is an 18th-century chest tomb of Portland Stone with a ledger slab of Welsh limestone. It contained William Caslon the Elder (1692-1766) and his son William (1720-1778), who were distinguished type founders, after whom a typeface is named.

The burial grounds are described by Mrs I Basil Holmes, in her *London Burial Grounds*, published in 1896, as being;

*'...in two parts. The size of the whole grounds, nearly one and three quarter acres. The piece round the church is closed, and full of large later tombs, ivy being planted most profusely. There is a great deal of rubbish in it. The part on the north side was laid out as a public garden in 1878, and is maintained by the vestry.'*

The church was built over a semi-subterranean crypt, constructed of brick, as an integral part of the church structure. This space was originally prohibited from use for burial but this did not remain the case for long. The Vestry minutes hold no mention of burial within the crypt below the church until 1740, when the fees are listed.

By 1810 the vaults were being described as large and commodious but dark, damp, neglected and highly offensive. Sufficient ventilation had not been secured and wooden coffins rather than lead had been admitted. The Committee recommended

that funerals of opulent individuals should be promoted in the vaults and churchyards; that the fees for interment in the vaults and churchyards should not be enhanced, that hereafter no corpse be permitted to be placed in the vaults except in leaden or metal coffins and that apertures should be made in the walls at the east and west ends of the church, of 3 ft in diameter to ventilate the vaults.

In 1853 the Vestry Minutes record that a petition to Viscount Palmerston, Prime Minister at the time, for an extension of time for closing burial grounds and vaults of this church was turned down: burials (including those in the vaults) to be discontinued at the end of this year and the vaults sealed. The sealing of the vaults was usually carried out by infilling with dumps of soil, domestic refuse and building rubble.

### **The parishes of St Luke's and St Giles' Cripplegate**

The London watchmaking trade had located its construction sector within the parish of St Luke's and the adjoining Clerkenwell around the middle of the 18th century. By the end of the 18th century the watchmaking artisans in St Luke's were estimated at 1,000.

In the 18th and 19th centuries many of the poorest in London were Irish. Francis Place, commenting on a description of the 'dissolute manners of the Irish in St Giles in 1816 said:

*'this account is no doubt correct, and is a fair picture of the manners of a much larger proportion of the people half a century ago. Such people...are now only to be found in a few places, such as the back settlement of St Giles, some places in the parish of St Luke and Ratcliffe Highway, and almost wholly among the Irish. The poorest and most dissolute people in Spitalfields are several grades above the mere Irish'.*

The parish was 'laid out in numerous streets and squares, covered with buildings in every direction, and has become one of the most extensive, and populous parishes in the suburbs of the metropolis' according to Lewis, writing in 1840.

In 1798 the Commissioners for Assessed Taxes was established. This divided houses into five categories, depending on the total amount of assessed tax they paid

each year. This cannot be directly related to annual income but as some tax collectors added additional notes it can be equated.

*Table 2.1 Category of tax paid equated with annual income*

Category	Tax	Annual income
I	under £1	£61
II	£1-under £2	£66
III	£2-under £5	£79
IV	£5-under £10	£128
V	£10 and over	over £200

Old Street parish had only 16.6% of category IV and V houses and could therefore be classed as a poor parish; all the parishes within the city had over 50%.

### **The parish registers**

#### ***Burial registers***

These are held, with baptismal and marriage records, at the Greater London Record Office, where they are available only on microfilm (Films X27/1A, 1B, 2, 13-15). They are arranged in monthly, or part monthly blocks, interspersed with sections for christenings and marriages. The format is as follows:

- name
- man/woman/child (not age)
- cause of death (eg consumption, ague, dropsy, smallpox, 'age')

There is no indication of place of burial until 1804 when exact ages and addresses of deceased are also introduced although not uniformly. Apart from a 16-month gap between August 1805 and December 1807 this system continued in place until December 1812, after which it was replaced by printed register pages which did not require information of this kind. Places of interment are indicated by codes:

- NBG (presumably north - or back burial ground)
- SBG (south - or front burial ground)

- PHG (Pest House Ground)
- BCY (?Back - or north Church Yard)
- FCY (?Front - or south Church Yard)

In the period 1804-5 and 1807-12 there were 18 vault interments. The commonest causes of death for these were consumption and convulsions, and there were also cases of dropsy, death in 'childbed', and 'shot himself' (presumably unintentionally and not a suicide). The burial registers for some of these people sometimes mention cause of death some of which we recognise today such as age or cancer, others like decline, dropsy and mortification are far less obvious.

*Table 2.2 Cause of death as recorded in the burial registers*

Coffin Number	Forename	Surname	Cause of Death
991	James	Lumley	Abscess
350	Bowes	Todd	Abscess
913	Thomas	Godman	Age
656	Mary	Williamson	Age

449	George	Jeffreys	Shot himself
1149	Michael	Lan	Sudden death
1147	Michael	Lan	Sudden death
1146	Thomas	Lan	Suddenly

### *Place of residence*

It has been possible to identify the address at the time of death for 252 individuals through examination of the Burial Registers. Where an asterix appears adjacent to an address in the table it indicates that it is located in the parish of St Luke's Church. The total number of individuals who resided in the parish at the time of their death was 140

*Table 2.3 Place of residence of named individuals*

Coffin number	forename	Surname	Address
303	Rebecca	Sowter	Albert Place, Clapton
1304	Jane Elizabeth	Campion	Albion Place, New North Road

### Occupation

The Burial Registers record the occupation of only two of the individuals identified during fieldwork. They are the Reverend Trefusis Lovell '31 years rector of this parish' and Henry Lovell whose occupation is listed merely as 'church'.

### Other evidence

No Searchers Reports or Burial Fee Books, which could have provided comparable information for the years before 1804 and after 1812, appear to have survived at the GLRO, Finsbury Library of Guildhall Library.

The GLRO does however hold a *Register of Headstones in back churchyard c 1753-1855* which records inscriptions on stones, name, person or family and plot number (Film X27/16) and *Monumental inscriptions in St Luke's churchyard*, with index (1877), described as similar to that for the back churchyard, and therefore presumably relating to the front churchyard (Film X27/18).

## **The Vestry Minutes**

12 June 1734

A well to be made on the Back Burial Ground to drain the water out of the same.

27 August 1734

Burying dues in back burial ground south side 13s 6d; middle ground 7s; pensioners at the lower end 2s 8d. Two corpses are not to be buried in any one grave, and the same not to be less than 4 ft deep (no mention of vaults)

9 May 1735

Ordered that the Pesthouse burial ground be shut up (unhealthful and noysance)

30 March 1736

References to burial in any of the parish burial grounds (no mention of vaults).

7 June 1739

References to burial out of the churchyards or burial grounds belonging to the parish (no mention of vaults)

5 December 1740

Burial fees.

Payable to churchwardens for:

- burial in the vaults under the church £2
- ground on the southern part of the churchyard £1 (would have been more expensive because entrance to the church was on that side and therefore burial there would have been more 'visible')
- ground on the northern part of the churchyard 14 s
- in the southern part of the burial ground 8s
- in the northern part of the burial ground 6s
- Pesthouse (pensioners excepted) 3s 6d
- Ditto If under 10) 2s 6d
- For every vault to be enclosed under the church to be purchased of the parish at per foot square 3s
- For every vault to be purchased of the parish in the churchyard or burial ground at per foot square 4s

Payable to the Clerk for:

- burial under the church, 2s 6d
- in the churchyard, 9d

- in the other grounds, 6d
- burial in the vaults, 2s
- in the ground on the south part of the churchyard 2s
- ditto on the north part 1s 6d
- south part of the burial ground 1s 6d
- ditto north 1s
- Pesthouse 1s (located to north-east of St Luke's church)

Payable to the bearers for:

- burial in vault to each bearer 2s
- in each burial ground ditto 1s

Burials were certainly being made in the vaults by December 1740, but apparently not before (the new scale of charges of the same date could have arisen from the introduction of burials there as an alternative option).

#### 3 March 1741

Pesthouse behind the garden of Allen's (?Alleyn's) Almshouses.

#### 17 October 1743

Vault made in south churchyard by friends of Mr Wells

ordered that in future no person shall be buried nor any ground broken in the church or churchyards or any of the burying grounds belonging to this parish nor any vault shall be suffered to be made nor any gravestone or monument shall be laid down or set up until the friends and relations of the deceased shall have first paid the church dues to the Churchwarden etc.

#### 20 June 1751

Pesthouse burial ground be shut up till orders to the contrary. Burials in the Back churchyard 'as usual'.

#### 1 June 1758

Ordered that the back burial ground be shut up till further order and that the Pest House ground be opened for burials and the ground levelled.

#### 30 November 1758

Agreed that a reward of £5 be given to any person or persons who shall at any time detect and apprehend any person stealing Corps out of any of the Burial Grounds belonging to the church, to be paid upon conviction thereof by the churchwardens.

12 October 1810

Report of a committee appointed on 30 May 1809 re the state of the churchyards and burial grounds belonging to the parish, and fees required for interment.

That the vaults beneath the church (are) large and commodious but dark, damp, neglected and highly offensive. Sufficient ventilation not having been secured and wooden coffins having been admitted.

That the whole of ground surrounding the church is denominated the north and south churchyards, which are also neglected; that there are upwards of 40 tombstones much out of repair, being decayed, broken and their owners unknown.

That the burial ground on the north side of the churchyard is also divided into two parts by a row of trees and also called north and south Burial Grounds, and of which the north part is higher than the south, and for interments wherein lower fees are required. Similar neglect displayed, and immediate improvements required.

That the ground commonly called the Pest House Ground is situated in Pest House Row (and) is a large plot of ground principally appropriated for the interment of paupers - but which by a change of name and a trifling expenditure may be rendered convenient and productive.

The north burial ground is nearly filled. May need to purchase additional churchyard at considerable and burdensome expense.

The Committee recommends that funerals of opulent inhabitants should be promoted in the vaults and churchyards; that the burial grounds be made convenient for persons in middling circumstances, and that the Pest House Ground should be also so improved as to be acceptable for the interment of the poor inhabitants.

That for these purposes the committee think that the fees for interment in burial grounds should be more equalised rather than increased, and that very moderate fees should be charged for interment in the Pest House Ground.

That for these purposes the Committee recommend that apertures should be made in the walls at the east and west ends of the church of 3 feet in diameter that they (sic) may be ventilated; that the grave diggers be employed to collect all the remains of the dead and inter them in one hole; and that hereafter no corpse be permitted to be placed in the vaults except in leaden or metal coffins.

#### Burial fees

- burial in vaults and churchyards £2 10s

- south burial ground 12s
- north burial ground 9s
- Pest House 4s
- For every vault to be purchased under the church to be enclosed at per square foot 5s

That corpses of all persons whose families have vaults or graves with flat or head or footstones, although they were non residents at the time of their death, shall be regarded as resident parishioners and pay only a single fee.

Estimated costs

- digging holes and for removing remains from the vaults 5s 5d
- apertures to the vaults in the church £100

24 July 1849

Parochial interments: re north burial ground, including poor burial ground in Bath Street.

25 June 1850

Metropolitan interments bill noted, re mortuary fees payable, now before the lords.

10 September 1851

Repairs (unspecified).

27 April 1852

Repair needs itemised. Include limewhiting the walls leading to the vault, 10s 6d.

27 October 1853

Burial Grounds Interments. Petition to Viscount Palmerston for an extension of time for closing burial grounds and vaults of this church turned down: burials (including those in the vaults) to be discontinued at the end of this year. Vestry inclined to remonstrate on grounds that Privy Council were violating the intention of the Legislature. Signatures transcribed into the Minutes, but nothing came of it.

*Table 2.4 Burial fees, extract from Joseph Turner, Burial fees of the principal churches, chapels and new burial grounds in London and its environs...and...all information for undertakers c 1838*

	parishioner	non-parishioner
North Ground	0 12 6	0 14 3
Church Service	0 10 0	0 10 0
Under 10 years	0 9 6	0 11 3
South Ground	0 17 0	1 0 9
Under 10 years	0 13 0	0 16 9
Service	0 10 0	0 10 0
Front Ground	3 10 0	3 13 9
Vault, Bell, &c	4 0 0	4 5 0

Burial times: week days from Lady-day to Michelmas, half past 4, Michelmas to Lady-day, 4; Sundays 4 - if in Church, half past 2 0'clock. Early Dues - Fitting.

## Faculties

The index of the diocesan Vicar General's Act Books at Guildhall Library MS 9532/4-10 (1725-1826) were checked as part of the desk based assessment (MoLAS 1996); neither St Luke's nor St Giles was mentioned, so it was concluded that the church must have been subject to the St Paul's Dean and Chapter in this respect. This was confirmed by checking the St Paul's' faculties (also at Guildhall Library) up to 1796 (MS 25, 664/3-5). However, they related only to appointment of clergy etc, and from 1840s St Paul's Faculties were absorbed by the diocesan system.

At Guildhall Library only the faculty papers from 1870 have been sorted and indexed (before that date only the faculties themselves are given in the Act Books, as above, without supporting petitions and papers).

### 1877

Underpin south and east walls and major repairs, MS 18, 319/86

### 14 March 1877

Faculty to alter and improve the parish church: underpin S and E walls and pier supporting the E column on the E side...the resealing of the whole of the ground floor of the church according to the plan annexed. At the same date a petition of the laying out of the churchyard as ornamental gardens: removal and setting back carefully of such memorial stones as may be necessary for the construction of pathways...that none of the bodies or remains will be removed from the churchyard.

1937

List of tombstones in disused burial ground /101

This item was called back from GL by the Diocesan Register who have retained it.

1946-9

LCC to maintain and develop churchyard /113

1949

Layout of churchyard as gardens

Petition granted for laying out the southern part of the burial grounds in the manner shown on the plan. Earlier works of the kind previously carried out by the LCC. To lower tombstones and cover the area with soil to level up; in the place of brick vaults to reduce the brickwork and replace the top slab and cover with soil. Also references to work on the 'rear portion' beyond Mitchell Street. Only tombstones in 'bad' condition to be moved.

1960

Re dangerous structures, notice /162

Faculty granted 1 June 1960 for demolishing the church except the tower to ground level as a dangerous structure, and removing scheduled items to St Giles. Removal of tablets to the tower. Nothing said about the vaults. Schedule of memorial tablets (of which only a few).

1964-5

Re-interment and bricking up of vaults (GL MS 29441/376/1)

A petition from the rector dated 27 November 1964 concerning the unlawful entry of thieves and tramps into the roofless precinct on many occasions since the partial demolition of the nave. While blocking windows and building up openings in the brickwork etc it had been found that coffins had been disturbed and in one instance the lead interior had been taken apart from the case and the top forced off to reveal the human remains in an advanced state of decay. These were immediately sealed in a zinc coffin. The name plate removed from the damaged coffin was inscribed: 'Mrs Esther Tomkies, died 2 December 1953??? in her 53rd year.' [This inscription is clearly incorrect. During the archaeological works this zinc coffin was located in bay 3 immediately inside a bricked up entrance. The contents of the coffin were identified as an ageing adult female, stature 153.39 cm, who had slight degenerative joint disease and gum disease: she had lost half of her teeth in life. The intact lead coffin of a child (1202) was found at the eastern end of bay 3; it bore the inscription 'Esther

Henrietta Tomkies died 17th July 1828 aged 3 years and 9 months.' Her address in the burial register was recorded as Fountain Place, City Road. The two may well have been related.] A builder has placed an estimate of £77 as the cost of bricking up the remaining openings into the crypt to prevent further vandalism. This would deter attempts to gain entry into the crypt from basement level, and work already done in July 1964 (no faculty appears to be available for this) should in turn deter attempted entries from ground level.

A plan of the crypt showing the position and bricking up of the remaining openings exists. Permission requested to confirm placing of the remains in a new coffin to remain in the same position as the old one, and to authorize bricking up.

A memorandum by H Norman Haines, Diocesan Architect at Fulham Palace, dated 10 November 1964 helpfully makes clear that Mrs Tomkies died in 1853 not 1953, and notes that the first break in at the church was reported in November 1960 and again in August 1961. Doors were broken down and there had been interference with the contents of the crypt. The only access to the latter was via the south-west porch and staircase, but entry had also been forced through holes made in the nave floor. Similar activities were reported in April 1964 when a thorough search of the crypt was made with the aid of temporary lighting. A further inspection in July, while contractors were bricking up walls and sealing the holes in the floor with concrete slabs, revealed that coffins had been disturbed (as reported by the incumbent).

In August instructions were received from London Diocese to remedy the damage and secure the coffins from further disturbance by placing them at the east end of the crypt and sealing the openings with brickwork. The London Necropolis Company was to be employed in resealing and casing the human remains and moving the coffins out of harms way.

From a preliminary shallow excavation it became clear that the task was going to be much bigger than expected, in that once the coffins in the disturbed area were removed to side vaults another layer of coffins would be revealed beneath them. The Necropolis Company estimated that the earth floor of the crypt might cover three layers of coffins spread evenly over the whole area. It was agreed that the disturbed coffin should be returned to their original positions, while the others were to be left and the areas where the coffins were found was to be completely sealed off.

On 13 November 1964 the Registrar reported to Haines at Fulham Palace that the bricking up of the four openings into the crypt had now commenced (the plan only

colours two blockings though the position of the other two seems pretty obvious: 'at the foot of the northern staircase and between the second and third chambers).

#### 1965

Transfer of burial ground and pest house (GL MS 29441/376/1)

A Faculty to enable the GLC to exercise powers of management under the provisions of the Open Spaces Act 1906 in respect of St Luke's pest house burial ground. Involved 'conveyance' of the burial grounds from the incumbent to the GLC subject to the preservation of existing monuments, if any, for the sum of £7500. The Council agreed to lay out the burial ground as an open space within the meaning of the Act. No indication is given of the site of the pest house and burial ground.

#### 1975

Redevelopment of churchyard (GL MS 21544/376)

Letter of 17 July 1975 from the Islington borough solicitor to the Diocesan Registry noting that the Council was considering the inclusion of the former church and churchyard of St Luke in a plan for the proposed Finsbury Leisure Centre, and that he has been advised that a Faculty is required before the intended work can be carried out to the north of the footpath between Mitchell Street and Ironmonger Row, which is consecrated ground. Possible uses included a blind garden or a bowling green, it being understood that no building was permissible. Could the Registrar please say whether or not the Chancellor would be likely to object in principle.

The Registrar replied on 29 July 1975 that the Chancellor has no objection subject to the Diocesan (?Disused) Burial Grounds Act and the advice of the Diocesan Advisory Committee.

#### 1989-91

Removal of human remains (GL MS 29441/376/2)

On 8 March 1989 an application was made for a dispensation order for leaving undisturbed human remains under part of St Luke's churchyard which was to be used as a car park, and for their removal under part of the churchyard, edged orange on plan A, where an extension of the church was proposed, and also for their removal from the crypt. All removed remains were to be reinterred in the part of the churchyard marked blue.

The plan shows that the orange area, the site of the offices, lay directly north of the south east end of the church between Helmet Row and Ironmonger Row. The whole of the church site itself is coloured green. The intention seems to have been to

sell the church site to the Patten makers as the location for their proposed livery hall: the office extension in the churchyard to the north was part of this scheme.

On 28 April 1989 chartered surveyors informed the Diocesan Registrar that 'within the crypt the coffins and remains are covered by an earth fill and therefore, as yet, are inaccessible.'

On 20th July 1989 the Home office informed the Diocesan Registrar notes that the Secretary of State had issued directives for the removal and reinterment of human remains from the church (area coloured green) and the part of the churchyard marked orange.

Argument between the Home Office and the Registrar early in 1990 about whether the church, and which part of the churchyard, was to be included in the dispensation, or whether they should be covered by other provisions.

On 26th March 1990 the Registrar asked the Home office to omit any reference in the dispensation order with regard to the crypt, feeling that it would come under the provision of earlier directives given by the HO.

On 17th August 1990 HO Registrar a new draft dispensation order covering the entire area except the two areas where remains will be disturbed; the churchyard area in orange (for the office extension) and the church itself.

On 27th September the Registrar notified the Home Office that the order was correct as drafter, and asked for the order to be issued.

On 9th May 1991 the Home Office wrote to the Registrar enclosing the dispensation order (dated 8th May), excluding the areas bounded by thick orange and green lines.

### **Other Sources**

A bound book entitled *Metropolitan borough of Finsbury: St Luke's burial ground* contains an alphabetical index of persons buried at the south burial ground: some 1180 entries relating to 161 tombs, details of whose inscriptions (where still legible) are given, pursuant to the Open Spaces Act 1906. Gummed onto the front endpaper is a notice by the borough of Finsbury, dated 17th June 1937, of its intention to apply for a faculty for permission to remove and change position of tombstones or monuments in the burial ground adjoining St Luke's being at the front or south of the church abutting Old Street. Persons with families interred there are invited to communicate.

A bound book entitled *Minute book of the St Luke's church and burial grounds improvement committee, 1875-8* contains the following information:

Schemes of November 1875

For repairing fabric of the church, reseating the interior and laying out burial grounds attached.

14th March 1878

Visit of Dr Tristram, Vicar-General of the bishop of London, to inspect the burial ground at the back of the church, including the alterations made (gravestones set back from the centre of the burial ground to the side at the northern end). His view was that all inscriptions on the stones should be preserved and not buried in soil, and that additional powers would be necessary for removing 'such stones as were not actually in the way of such paths as were shown in the plan'.

19th March 1878

Agreed that flagstones be laid down in the front churchyard and opposite the west entrance to complete the whole area between the church and the wall of the graveyard.

23rd February 1877

Tristram's response to a petition from St Luke's to underpin south and east walls etc, including reseating, removal of upper gallery and resealing of the ground floor.

Letters from rector to Tristram in 1895

12th November, concerning a scheme to transfer the back burial ground to (?borough of Finsbury) for them to use and keep in order and retain the front burial ground. Is a faculty necessary for this. The Vestry thinks that the rector can do it only on his own authority, but he is concerned about an annual payment to him from the churchwardens of £200 as fees (as per Act of 6 George II, cap 21) for all burials and for making vaults and interments in the crypt of the church. This has not been paid for some years (though after burials ceased at the church it had first been paid from other sources). But he doesn't want to risk prejudicing his successors' rights to the payment by transferring the freehold. Tristram's reply not recorded.

## CHAPTER 3 THE ARCHAEOLOGY OF THE CRYPT AND BURIAL GROUND

*by Angela Boyle and Ceridwen Boston*

### Introduction

Structures existing within the churchyard and the crypt of St Luke's church were recorded prior to and during excavation. This chapter describes the upstanding chest tombs, ledger stones and recumbent tomb stones found within the churchyard, and the private vaults subdividing the interior of the church crypt (Figs 3.1-3.6). cursory descriptions of the structure of the crypt itself is included but these are not intended to be comprehensive.

### The Churchyard

At the time of the archaeological recording action the churchyard surrounding St Luke's church was enclosed by Grade II listed railings and gates of 19th-century date, with a further enclosed area to the north of Mitchell Street. The churchyard immediately surrounding the church was split into two areas - a northern and a southern churchyard. Most of the chest tombs were located in the northern churchyard. The Grade II Carlson tomb was located in the centre of the southern churchyard. Plane trees<sup>2</sup> were planted along the perimeter and in the central area of the churchyard. A horse chestnut tree was situated on the north side opposite gate G1(N). A survey of upstanding extra-mural tombs was undertaken by architects Levitt Bernstein Associates. Numbers prefixed by GRN and GRS refer to this survey. Chest tombs that fell within the excavation area were also recorded by archaeologists. These describe both the above and below-ground structure of the tombs and brick shaft graves. The architect and archaeologist's surveys have been combined where appropriate.

---

<sup>2</sup> Any of several trees with broad leaves and bark that comes off in patches

### ***Boundary walls and railings***

Churchyard railings of painted cast iron welded to a cast iron coping set onto a low brick wall of yellow stock bricks are laid Flemish bond externally and English bond internally, and pointed in lime/sand/cement/mortar. The height of this wall is stepped as Helmet Row and Ironmonger Row fall away north/south. The ground level within the churchyard, however, remains level until the southern boundary becomes a low retaining wall. This section of wall on Old Street is faced with panels of cast iron. On the Old Street front, railings have palmette finials with fluted standards, and a mid rail with half height railings and scrolled brackets and backstay of cast iron. The gate piers to the east and west on this front (G2S; G3S) are of four clustered standards each side with lamp standards. The west gates (G3S) each have a cast iron shield lettered 'St Luke. Middlesex. AD 1852'. On Helmet Row, Ironmonger Row and Mitchell Street, railings are of a plainer design with arrowhead finials and no mid rail. Gate piers are formed of clustered standards in Helmet Row and Mitchell Street. Scrolled brackets on brick piers are present at each bay and lamp column. These have a plainer design on north, east and west sides. Generally, railings are stained with some graffiti.

### ***Pathways***

The pathways which existed at the time of the archaeological watching brief appear to be those which are represented in Richard Horwood's map of Regency London produced between 1792-9 (Laxton 1985). The gaps which appear in the plan of exposed graves seem also to conform with this (Figure 3.3).

### ***The churchyard vaults and brick-lined shaft graves***

In addition to simple earth-cut graves, St Luke's churchyard contained a number of extramural vaults and brick-lined shaft graves for the interment of multiple individuals. There were fewer vaults in the churchyards than within the crypt. The northern churchyard contained four vaults and five brick-lined shaft graves, whilst the southern churchyard had six vaults and eight brick-lined shaft graves. In the northern churchyard, a total of 23 burials were recovered from within these structures, 13 of whom could be named. In the southern churchyard, 60 burials were identified, 23 being named individuals. A catalogue of the coffins and fittings may be found in Appendix 1.

The preservation of the shaft graves and vaults varied, but many were in a poor state of repair. Due to concerns over the health and safety of the excavators, many burials could not be hand-excavated *in situ*, but were recorded from above, prior to machine excavation. After being excavated mechanically, the spoil was checked for human remains, coffin fittings and grave goods. As a result of this imperfect system, there was some mixing of the skeletal elements of different individuals; as well as of coffin fittings. Destruction of less well preserved materials, such as textiles and wood, was inevitable in the circumstances.

From coffin plate inscriptions, it would appear that the vaults and shaft graves were in use between 1760 and 1850 - broadly the same time as the crypt vaults (Figures 3.1 and 3.2). Burial dates from 1778-1848 in the northern churchyard, and from 1755-1844 in the southern churchyard, with a lone outlier, a Mr Cole (shaft grave 126) being buried much later in 1880. Burial in the northern churchyard peaked between 1811 and 1820. In the southern churchyard, burial showed a bimodal distribution, peaking around 1790-1820, tailing off and peaking again between 1831-40. Overall, burial within vaults and shaft graves in the two churchyards was most intense between 1831-40 - a decade before the peak of the crypt vault burials. However, with the possible exception of the decade 1821-30, there is no indication that families abandoned burial within established churchyard vaults and shaft graves in favour of crypt burial. This is evident from the continued use of the churchyard vaults and shaft graves and the lack of duplication of surnames of those buried within the churchyard.

The brick vaults in the churchyard were characterized by arched roofs, with access to the vault interior via steps leading down to a doorway in one of the side-walls of the structure. In contrast, brick-lined shaft graves had access from above only. These graves were subterranean rectangular or coffin-shaped brick structures with their openings covered by a ledger or flat slab of stone. In some cases, the ledger of the grave was surmounted by a monument visible above ground, which bore inscriptions commemorating the deceased within the grave. Many such monuments have been moved or destroyed over time. Those chest tombs that survived were surveyed by the architects Levitt Bernstein Associates, and are described in the following pages. During a burial, the ledger would be lifted, and the coffin lowered into the grave from above, either being piled on top of earlier coffins, or being suspended by horizontal iron bars at different depths within the shaft grave.

Each vault or shaft grave belonged to a specific family group, who had paid considerable sums for the privilege of exclusive burial rights within this space. In late Georgian/ early Victorian urban churchyards, severe overcrowding of burials often occurred (although this was not so manifest at St Luke's church). Concerns about disturbance of the remains of recently buried relatives to make way for further burial led to a fashion amongst the middle and upper classes of lining graves with brick and surmounting them with monuments that were less easily disturbed than simple earth-cut graves. Vaults were a more expensive alternative. These monuments offered another avenue of social display through death ritual. The most desirable plots were the most visible to churchgoers, lining the paths leading up to the church in the southern churchyard.

Families in the 18th and 19th century set great store on burying family members close together. Thus, in most cases individuals within a grave or vault were usually related by birth or by marriage. More specific familial relationships may be established where coffin breastplates or inscriptions on the exterior of the graves identify the specific individuals interred within. Cross-referencing with parish and census records further elucidate these relationships.

### *The northern churchyard*

Seven vaults or brick-lined shaft graves discovered in the northern churchyard lacked upstanding monuments or above ground markers. It is assumed that these had fallen into decay and had been removed during maintenance of the churchyard. A catalogue of these structures is found below.

#### *Vault 104*

Brick arched vault under vestry. Constructed of red brick and mortar. Well constructed arch orientated north-south, facing church wall of southern crypt butts wall but was not tied in. No flooring material. No burials were present.

#### *Vault 109*

Rectangular east-west orientated brick vault constructed of pink-orange-yellow bricks and yellow-grey mortar. Vaulted roof. Entrance to the west blocked by upright limestone slabs. One brick step comprising a row of 10 bricks leading to entrance. Possible stairwell (559) butts vault on its western side. Arched roof 33 courses of brick high. Walls 20 courses high. Contained coffins 117; 118; 161 and 162.

#### *Vault 110*

Rectangular east-west orientated vault, with three steps leading down to arched entrance on eastern side. Constructed of yellowish-orange brick and hard yellow-grey cement mortar. Walls 24 courses. Arch 32 courses. Arch orientated north-south. Contained coffins 112; 113; 114; 115; 116; 212 and 213.

#### *Vault 174*

Rectangular, east-west orientated brick shaft grave under monument (5). Inscriptions on monument illegible. Composed of orange-pink brick and whitish-grey sandy mortar. Arched roof. Limestone slab sealing entrance approximately 1 m wide. Dimensions: length unknown; 2.4 m wide. Backfilled by yellow-brown sandy-silt (173). Contained a coffin (number unknown).

#### *Vault 208*

Rectangular east-west orientated arched vault, composed of 26 courses of mid-orange to yellow brick in wall, and 29 courses in arch. Four steps, composed of 2 courses of brick capped with limestone/sandstone slabs, lead down to the upper half of the vault on the eastern side. Dimensions: 2.15 m wide; 1.12 m high; doorway 0.9 m wide. Contained coffins 192; 193 and 194.

#### *Vault 456*

Rectangular east-west orientated vault close to church wall. Composed of red brick and soft grey, lime mortar. Thinner, redder bricks at the bottom of vault appeared to have been on a different alignment- possibly the foundation of the vault. Dimensions: 1.5 m x 2.3 m x 2 m (internal) Contained coffins 453 and 454.

#### *Vault 1303*

Rectangular east-west orientated brick shaft grave. Dimensions: 2.5 m x 0.87 m x 3 m (internal). 1.1 m wide (external width). Contained coffins 1304 and 1305.

### ***The southern churchyard***

#### *Vault 111*

Rectangular east-west orientated vault constructed of alternative header and stretcher course of pinkish-red brick. North-south arch. Internal dimensions: 1.42 m x 2.65 m x 2.65 m (floor to ceiling). Brick floor. Contained coffins 604; 605; 606; 607 and 608.

#### *Vault 124*

Rectangular east-west orientated vault with arched roof aligned north-south. Broken arch patched with ledger. Dimensions: 2.7 m x 2-m. Walls 0.23 m thick. Ledger (1.75-

m x 0.9 m x 0.1 m) covers grave shaft. Single course brick floor. Contained coffins 868; 869 and 870.

#### *Vault 126*

Rectangular east-west orientated brick shaft grave, capped with stone slabs and ledger for monument. Constructed of red bricks and yellow-white mortar. Dimensions: Under stone slabs - 1.18 m x 2.85 m x 0.9 m (external), Under stone slabs - 0.73 m x 2.36 m x >2 m (internal). Three rows of three horizontal iron bars extended cross-ways across the breadth of the grave, 0.5 m apart. Their function was to hold three rows of coffins. Contained coffins 619; 620; 621 and 622.

#### *Vault 144*

East-west orientated brick shaft grave, with slightly bowed walls, making the interior concave, and the exterior convex. Covered by three stone slabs (0.85 m x 1.6 m each). No evidence for roofing. Floor was natural brick earth. Dimension of grave: 2.8 m x 1.75 m x 1.6 m (external) Contained coffins 1166; 1167; 1168; 1169; 1170; 1171 and 1172.

#### *Vault 149*

Rectangular east-west orientated arched brick-lined shaft grave, composed of light-to-mid pink-yellow-red bricks. Capped with stone ledger, 0.1 m thick, with beveled edges; well finished (appears similar to table tomb). Walls 25 courses; arch 13 courses. Dimensions: 2.2 m x 0.66 m x 2.25 m (internal). Contained coffins 158; 187; 188; 190; 191 and 191.

#### *Vault 239*

Rectangular east-west orientated brick shaft grave. Wall thickness was 0.3 m. Covered with stone ledger with smooth finish and beveled edge, which overlay another stone slab (1.8 m x 0.95 m x 0.08 m). Dimensions of grave interior: 2.3 m x 0.8 m x 2.8 m. Contained coffins 807; 808 and 809.

#### *Vault 483*

Rectangular east-west orientated brick vault, composed of regular header and stretcher courses of brick and hard cement mortar on wall and arch. North-south orientated arch. Western entrance to vault via four steps, with brick side-walls and sloping two-piece stone cover. Walls at entrance way were bevelled (not seen in other vault structures). Floor covering: mortared stone slabs. Contained coffins 484; 485; 486; 487; 489; 490; 491 and 1312.

#### *Vault 496*

Rectangular east-west orientated vault, composed of 16 courses of red brick and grey concrete-rich mortar. Alternative header and footer courses. Entrance to the west through slab-blocked opening (1.83 m wide). Re-used inscribed slab used as lintel over entrance-way (1.02 m wide). To the east, were two more unmarked stone slabs (each > 0.6 m x > 1.3 m) Dimensions of vault: 2.05 m x 1.3 m x 1.15 m (internal) Wall thickness: 0.22 m Contained coffins 497; 535; 599; 600; 803; 804; 805 and 806.

#### *Vault 799*

Coffin-shaped east-west orientated brick shaft grave. Capped with stone slab. Bricks were two courses wide at base. Interior of grave horizontally divided into three compartments by limestone slabs. The lowest compartment was 0.6 m deep and 0.9 m wide, and contained coffin 800. Capped with limestone slab. The middle compartment was 0.6 m deep, and contained burial 798, coffin wooden completely decayed. Capped with another slab. Uppermost compartment filled with backfill.

Dimensions: width of 0.9 m; depth below ground level of 3.5 m; length unknown (extended beyond edge of excavation area). Contained coffins 798 and 800.

#### *Vault 828*

Probable vault against south-eastern corner of church. Constructed of red brick walls bonded with off-white lime-rich mortar. Had north-south orientated arched roof of yellow brick bonded with hard buff coloured mortar. This clearly belonged to different construction phase. Back-filled with rubble (possibly from collapsed vault arch). Dimensions of arch: 0.23 m x 0.11 m x 0.07 m. Top of arch 0.5 m below present ground surface. Dimensions of brick vault: 1.75 m x 4.5 m x 1 m. Contained no burials.

#### *Vault 1160*

Rectangular east-west orientated vault, constructed of red brick in alternative header and stretcher courses. Vaulted ceiling, and entrance hatch on eastern side. Brick flooring. Breached on the western side and re-pointed from outside with original bricks. Dimensions: 1.68 m x 2.3 m x 2.13 m (internal). 2.8 m x 2.1 m (external) Contained 1143; 1144; 1145; 1146; 1147; 1149 and 1201.

#### *Vault 1178*

Rectangular brick shaft grave orientated east-west. Not associated with any stone slabs or monument. Structure visible 1.2 m below modern ground surface. Dimensions: 2.6 m x 1.65 m x 1.8 m (external) Base of grave covered with re-used

tombstone of child (6 years) died 1711 (inscription incomplete). If the inscription is correct, the gravestone predates the foundation of the church by 22 years. This raises interesting questions as to its origins. No brick flooring. Charnel pit containing infant remains found beneath base of grave. Was not excavated further. Contained coffins 1176 and 1177.

#### *Vault 1179*

Rectangular east-west orientated shaft grave, constructed of brick courses. No associated slabs or monuments found. Structure was visible 1.9 m below modern ground surface. Dimensions: 2.3 m x 1.15 m x 1.9 m (external). Floor of flat-laid bricks. Back-filled - contained a considerable quantity of disarticulated human bone. Contained coffins 1180; 1181 and 1307.

#### *Upstanding monuments within the churchyard*

Ten upstanding chest tombs were still *in situ* in St Luke's churchyard and were recorded by the architects Levitt Bernstein Associates. They also recorded three horizontally laid tombstones and several tombstone fragments, which formed an edge to the grassed area north of the churchyard. These structures are prefixed with 'GR' in the text below. GR1-10N and GR14-17N were located in the northern churchyard, whilst GR11-13 were within the southern churchyard. These structures were all 18th- and 19th-century in date. During excavation, archaeologists also recorded the position of tombs and tombstones GR2N-GR10N and GR15, and described the subterranean structures beneath chest tombs that fell within the area of excavation. Six could be matched with the upstanding monuments and are grouped together below.

#### *GR1N*

Tombstone laid horizontally on raised plain brick plinth. Inscription on front (east) edge reads '*Family Vault of Mr J David Apples of Seward Street*'.

#### *GR2N or chest tomb 1*

Stone chest tomb with south side constructed of plain 19th century machine-made red and yellow brick (22 x 7 cm) bonded with hard, cement-based grainy mortar (stretcher bond). Remaining three sides of stone. All fairly plain and very worn. Inscriptions worn and illegible. East side had simple vertical roll moulding 7.5-9.5 cm in from the north and south edges. West side has traces of similar moulding. Four sides covered with overhanging stone coping (1.81m x 0.92 m). Monument set on plinth of three slabs of limestone. Set in gravel bed.

### GR3N

Chest tomb of the Wright family, dating to the 19th century. Delaminated on south-west and north-east corners. Side panels of plain yellow brick with stone plaque set into north side. Capped with stone slab.

### GR4N

Stone chest tomb of the Bishop family with pilasters at corners. Stone plaque on south face partly worn but reads '*...John Bishop...1820*'.

### GR5N

Stone chest tomb set on a stone plinth enclosed by 19th-century cast iron railings with steeple and urn finials. Fluted pilasters at corners of tomb. Stone oval plaques with fan decoration on each side. Inscriptions partly worn but south face reads '*Elizabeth Allen d. 1836*'; east side reads '*Thomas Allen d. 1818*'.

### GR6N or chest tomb 2

Stone chest tomb with granite set surround. Fluted columnettes at corners. Inscription on stone plaque worn on all sides, more so on south side and illegible. Relatively elaborate ornamental, classical design including a shield motif on each face. Overhanging stone coping (0.95 x 1.95 x 0.85 m) of relatively uncorroded stone. Beneath this structure lay vault 110.

### Vault 110

Rectangular east-west orientated vault, with three steps leading down to arched entrance on eastern side. Constructed of yellowish-orange brick and hard yellow-grey cement mortar. Walls 24 courses. Arch 32 courses. Arch orientated north-south. Contained coffins 112; 113; 114; 115; 116; 212 and 213.

### GR7N (or tombstone 3)

Tombstone with rounded corners (1.86 x 0.91 m). Laid horizontal, flush with the ground directly south of GR6N. Inscription partly worn. The only legible part reads '*....and Rachel...*'.

### Vault 555

Beneath this structure lay vault 555, a rectangular, east-west orientated brick shaft grave. Capped by three stone slabs, in turn overlain by single stone ledger (3). Brick floor. Vault dimensions: 2.5 m x 1.5 m x 3 m. Contained severely decayed wooden coffins 460 and 461.

*GR8N (or chest tomb 4)*

Stone chest tomb set on York stone paving in gravel bed. Relatively simple design with roll moulding at each corner of sides. Overlain by coping stone (1.91 x 0.93 m). Inscriptions worn on all sides. Only legible script was '.... in her 6th year...' on south face. Stone on west face very soft and corroded, inscription illegible. Stone on west face partly replaced. Vertical crack at centre of long side panels.

*GR9N*

Stone chest tomb set in gravel bed, date c 1754, fluted columnettes to same design as GR6N, inscriptions worn, top tomb slab has diagonal scoring and cracking running north-west-south-east with one mortar repair, concrete repair to north-west corner.

*GR10N (or chest tomb 5)*

Stone chest tomb on stone base, set in gravel bed and bounded by 19th-century cast iron railings with arrowhead and baluster finials. Fluted columns at corners. Stone plaques with Greek key fret decoration on all sides. Inscriptions on west and south sides worn and illegible. Overlaid by coping stone (1.95 x 0.91 x 0.11 m). Chest tomb 0.97 m tall.

*GR11S*

Located in the southern churchyard, south of the area of excavation. Tombstone laid horizontally on concrete base, inscription worn.

*GR12S*

Located in the southern churchyard, south of the area of excavation. Tombstone laid horizontally on stone and on concrete bases located directly south of GR11S, inscription worn.

*GR13S or chest tomb 6*

Located in the southern churchyard, south of the area of excavation. Chest tomb Grade II listed, 18th century, stone on stone plinth bounded by 19th century cast iron railings. Fluted columnettes at corners with slate plaques set in stone moulding on north, south and east sides.

Inscription on north face: *Mary Anne Carlson, wife of Henry Carlson son of Henry and Elizabeth Carlson born August 21st 1785 died March 31st 1816. Sacred to the memory of Henry Carlson esq. of Higham Hill, Walthamstow, Essex, only surviving child of Henry and Elizabeth, eldest daughter of William Rowl esq. of Higham Hill. Born Gower Street London May 15th 1786 died Boulogne sur..mer May 28th 1850'.*

Inscription on top of monument: *'William Carlson esq died Jan 23rd 1766 aged 74 years. Also William Carlson esq son of the above died Aug 17th 1778 aged 58 years. Also Miss Elizabeth Mary Carlson daughter of William and Elizabeth Carlson and grand-daughter of the above William esq who died Oct 30th 1780 aged 7 months and 18 days. Also Mr Thomas Carlson son of the above William Carlson died March 29th 1783 (?) Aged 56 years Also Miss Harriet Carlson daughter of Henry and Elizabeth Carlson and grand-daughter of the above William Carlson who died May ? 1785 aged 2 months and 9 days. Also Edmund Carlson son of the above Henry and Elizabeth Carlson died Oct 20th 1787 aged 12 weeks and 3 days. Here lyeth the body of Elizabeth Carlson widow of William Carlson esq the son of William Carlson senior esq who died Oct 24th 1795 aged 65 years'.*

Inscription on the south face: *'Thomas Hanby esq late of Hackney died Dec 1786 Aged 74 years. Here lyeth the body of Mary widow of the above named Thomas Hanby esq who died 14th day of January 1797 and also ....of Godfrey Shewell late of this parish and likewise daughter of William Carlson senior esq formerly of this parish'.* West side is blank.

*GR14N-GR17N (or group 101)*

Three complete tombstones and several fragments, all with moss growth, forming coping or revetment to the raised grassed area north of church. These formed a line parallel with the northern wall of the church edging the path. They appear to be tombstones and ledger stones relocated from different parts of the site during maintenance or landscaping of the churchyard in the past. Faint inscriptions were discernible on some of the stones but none were legible.

### ***Ledgers and recumbent headstones in the southern churchyard***

Following de-turfing and stripping of the topsoil of the southern churchyard, 41 recumbent stone slabs were revealed. These were found to be a mixture of ledger stones capping brick-lined shaft graves (n = 5), slabs forming components of the roof of extramural vaults (n = 2), recumbent gravestones (n = 5), and ledger stones not apparently covering vaults or shaft graves (n = 29). It is assumed that the last category were stone slabs that had either originally covered brick-lined shaft graves but had been disturbed and re-deposited, or were markers of earth-cut graves. Many of these ledger stones would originally have formed the base of memorials, such as crosses or inscription plaques, which have been lost since.

In most cases, it is unclear how far these stone slabs had been moved from their original position. In the majority of burials, *departum* plates inscriptions were absent or illegible, and most of the ledgers were very worn, rendering inscriptions thereon completely or partly illegible. Of the five ledgers that had traces of inscriptions on their upper surfaces, only three were even partly legible. None of the above inscriptions were found on the slabs capping shaft graves or vaults. Where inscriptions on ledger stones and headstones were legible and could be matched to *departum* plate inscriptions, it is clear that the stone slabs in the southern churchyard had moved at most only a few feet from their original positions. The names on two inscriptions of ledger stones correlated with inscriptions of *departum* plates found in nearby earth-cut burials, and matching inscriptions on three recumbent headstones suggest that these stones remained close to the family plots they originally marked. A catalogue of the ledgers and recumbent gravestones are recorded below.

#### ***Ledgers associated with Vaults and Brick-lined Shaft Graves***

Seven ledgers were found associated with extramural vaults and brick-lined shaft graves. These are 111; 124; 125; 126; 144; 149; and 239. These ledgers are characterized in the catalogue of these structures elsewhere in the text.

#### ***Ledger stones not associated with vaults or brick-lined shaft graves***

##### ***Ledger 121***

Ledger 121 was found overlaying part of the earth cut graves of 1009, 1014 and 1015. This 1.8 m x 0.83 m slab was inscribed with the following: *In memory of Mr William Clark of Islington who died 13th March 18.... Aged 70 Years. Also Mrs Mary Clark wife of the above Died 29th May 18..... Aged 72 Years.* Grave 1009 was found to contain the breastplate of Mary Clark (died 29/5/1844 aged 78 years). Despite the minor discrepancy in the age at death, the ledger stone was clearly commemorating the same individual. Osteologically, the skeletons 1014 and 1015 were analysed as being a prime to mature adult male and an ageing individual, possibly female. Although neither conclusively can be identified as Mr William Clark, it seems safe to assume that ledger 121 originally did mark this grave group, and that it had only shifted slightly from its original position over the burials. Dimensions of ledger: 1.8 x 0.83 m.

### *Ledger 123*

Ledger 123 squarely overlay two unnamed burials (871 and 872), and probably was originally associated with them. The ledger bore no inscription. The slab had a beveled edge, suggesting its use as the base for a memorial or table tomb.

Dimensions: 1.8 m x 0.9 m x 0.08 m.

### *Ledger 127*

Ledger 127 did not overlie any burials, but lay close to burial cluster 827, 861 and 862. The latter two were graves of Capt. Alex Francis Bailey (year of death unknown), and Mrs Elizabeth Baillie, died 1810, respectively. There was no inscription on the ledger. Dimensions: length = 1.75 m; depth = 0.12 m.

### *Ledger 128*

Ledger 128 partly overlaid a cluster of burials of the Richardson and Allan families, dated between 1111 and 1824 (933-937). A very faint inscription was detected on the ledger but was too worn to be legible. It is thus impossible to establish whether the ledger did originally mark these burials, but this is highly probable given its location.

Dimension of ledger: 1.9 m x 0.95 m x 0.12 m.

### *Ledger 129*

Ledger 129 partly overlaid two burial groups, one of the Fuller family (burials 890; 891; 927; 928), and a cluster of four unnamed burials (burials 929-932). No inscription was detected on the ledger so it cannot be established to which of the groups the ledger was associated. Cement on the top of the slab suggests that it had been surmounted by a memorial. Dimension: 1.8 m x 0.95 m x 0.1 m.

### *Ledger 131*

Although ledger 131 did not overlie any burials, it lay very close to a cluster of three unnamed graves (995, 997 and 998). The slab bore no inscription. Dimensions: 1.8 m x 0.9 m x 0.09 m.

### *Ledger 132*

Ledger 132 did not overlie, or even lie in close proximity to any earth cut graves or structures. Thus, its association with specific graves or structures within the churchyard is unclear. The ledger bore no inscription. Dimensions: 1.9 m x 0.9 m x 0.11 m.

### *Ledger 133*

Ledger 133 did not overlie any burials, but did lie in close proximity to a cluster of six burials (1007, 1008, 1011-1013). Burial 1008 was of a George Scott, who died in

1766. The other burials are unnamed. Ledger 133 bore no inscription. Dimensions: 1.75 m x 0.8 m.

*Ledger 134*

Ledger 134 partly overlay two unnamed burials 1306 and 877, and probably was originally associated with them. No inscription was observed on the ledger. Dimensions: 1.8 m x 0.8 m x 0.12 m.

*Ledger 136*

Ledger 136 did not overlie or indeed lie close to any burials. Its association with other contexts in the churchyard is therefore unclear. The slab bore no inscription. Dimensions: 2 m x 1.5 m x 0.13 m.

*Ledger 137*

Ledger 137 did not overlie, or lie in close proximity to any earth-cut graves or structures. Its original provenance is thus unclear. The slab bore no inscription. Dimensions: 1.8 m x 0.85 m x 0.11 m.

*Ledger 138*

Ledger 137 did not overlie, or lie in close proximity to any earth-cut graves or structures. Its original provenance is thus unclear. The slab bore no inscription. Dimensions: 1.8 m x 0.9 m x 0.1 m.

*Ledger 139*

Ledger 139 squarely overlay the grave of a Mr William Linsley, who died in 1838 (1022). It probably marked his grave. The ledger bore no inscription. Dimensions: 1.95 m x 0.95 m x 0.1 m.

*Ledger 140*

Ledger 140 directly overlay a cluster of unnamed graves 1016-1021 and 1297, and probably did originally marked this grave originally. The slab bore no inscription. Dimensions: 1.8 m x 0.9 m x 0.08 m.

*Ledger 141*

Ledger 141 did not overlie any earth cut graves, but lay very close to the cluster of unnamed graves 1108, 1110 and 1114, with which it may have originally been associated. The slab bore no inscription. Dimension: length unknown; breadth = 0.85 m; depth = 0.08 m.

*Ledger 142*

Ledger 142 did not overlie any graves or structures. It was found located between two clusters of burials (graves 1027 and 1028; and graves 1118-1120 and 1298). Burial

1120 contained a breastplate bearing the name of Doherty (died 1818). It is unclear to which group the ledger originally belonged. The slab bore no inscription. Dimensions: 2.0 m x 1.05 m x 0.1 m.

#### *Ledger 143*

Ledger 143 was not found overlaying any graves but was located close to a group of three unnamed burials (1038-1840). It is impossible to establish if the ledger and the graves are associated, but their spatial proximity makes this probable. The slab bore no inscription. Dimension of ledger: 1.95 m x 0.8 m x 0.1 m.

#### *Ledger 145*

Stone ledger 145 bore no inscription. The slab was not found overlying an earth cut burials, but did lie close to two burial clusters: 1184 and 1185 (the grave of Sarah Boorman, dated 1847), and the unnamed cluster of 1183, 1186-1187. It is impossible to determine to which group the slab belonged as the slab bore no inscription. Dimensions: 1.85 m x 0.75 m x 0.15 m.

#### *Ledger 146*

Ledger 146 did not overlie any earth cut graves or structures, nor lay in close proximity to any burials. Its original association is therefore unknown. The slab bore no inscription. Dimensions: 1.88 m x 0.97 m x 0.1 m.

#### *Ledger 147*

Ledger 147 was located at the edge of the excavation. The full width of the slab could not be ascertained, as it underlay the bulk edge. The ledger did not appear to overlie any burials, but was located close to two unnamed burials, 1286 and 1287. No inscription could be discerned. Dimension: length = 1.97 m; depth = 0.11 m.

#### *Ledger 148*

Ledger 148 did not directly overlie any burials, but was located close to two unnamed burials 1286 and 1287. No inscription could be discerned. Dimension: 1.85 m x 0.9 m x 0.07 m.

#### *Ledger 150*

Ledger 150 was found in position with brick supports. However, it did not overlie any graves, but lay close to a cluster of unnamed burials 1279-1281, 1284 and 1285. No inscription was discerned. Dimensions: length = 1.85 m; breadth = 0.8 m.

#### *Ledger 151*

This western part of this ledger extended beyond the edge of the excavation. A faint inscription was present but was too worn to be legible. Ledger 151 overlay a cluster of

five graves (1266-1270). Although there were no inscriptions from either the ledger or the burials to match the two, it is probable that the ledger did originally mark these burials. Dimension of ledger: 1.8 m x 1.03 m x 0.08 m.

#### *Ledger 152*

Ledger 152 partly overlay unnamed burials 1250-1254, and may well have been originally associated with them. No inscription on the ledger could be discerned.

Dimensions: 1.81 m x 0.9 m x 0.1 m.

#### *Ledger 153*

Ledger 153 squarely overlay unnamed burial 1249, and it is highly probable that it was associated with it. The ledger bore no inscription. Dimensions: 1.87 m x 0.94 m x 0.1 m.

#### *Ledger 154*

Ledger 154 lay between two clusters of burials 1230- 1233 (1233 is the burial of Mr Thomas Goodwin, died 1762) and 1234-1239. Lacking any inscription, it is impossible to determine to which burial group this ledger originally was associated.

Dimensions: 1.86 m x 0.85 m, x 0.09 m.

#### *Ledger 164*

This ledger was not found overlaying any graves, but was located close to a cluster of burials (1122-1124; 1155; 1162). Grave 1162 contained the only *departum* plate of the group: The breastplate inscription read: *Mrs Ann Holloway died 27 December 1811 aged 45 years*. The inscription on ledger 164 was very worn and only partially illegible. The following lettering could be discerned: *John Hol.... .....pt ' 1817*.

*Aged.....Ann Co..... Daughter of the ..... August 1832 Aged ..... Sarah Elizth..... daughter of the ..... Jany 1837 Aged ..... ne Sarah .....Feby 184.....*

Although the inscriptions did not match in terms of date of death, the Christian name Ann recurs. Although the surname on the ledger stone is incomplete it is likely to be Holloway, given the proximity to grave 1162. Ann Holloway (1162) appears to have been an early burial within the Holloway family plot, preceding the burial of the individuals commemorated on the ledger. Dimensions of ledger: 1.8 m x 0.88 m x 0.1 m.

#### *Ledger 165*

Ledger 165 overlay the feet of the skeleton 1117, and probably originally overlay the grave more squarely than it did latterly. A small amount of inscription on the ledger

read as follows: *P 1810*. Unfortunately, there were no *departum* plate inscriptions to link the burials to this inscription. Dimensions: 1.65 m x 0.75 m x 0.09 m.

#### *Ledger 167*

Ledger 167 squarely overlay the burial of 1115. It probably marked this grave originally, but there is no inscription either on the *departum* plate or ledger to establish this unequivocally. Dimensions: 2.0 m x 1.02 m x 0.09 m.

#### ***Recumbent headstones***

Five of the stone slabs in the southern churchyard were found to be recumbent headstones. All bore inscriptions, which are reproduced in the text below. These slabs seem not to have been moved deliberately, but were left where they had fallen. Those that had fallen forwards overlay the graves they had originally marked, whilst those falling backwards were found adjacent to the graves with which they were originally associated.

#### *Recumbent headstone 130*

This recumbent headstone was found overlying the lower legs and feet of skeletons in grave 888 and 889. Grave 888 contained a partially legible breastplate, which read: *Charles .....late of .....in the County of D.....born 24 August 1784 obit 25 February 1830*. The other burial was an unnamed prime adult female. The breastplate inscription matches the inscription on the headstone, which read: *Sacred to the memory of Charles Read Esq ....e of Downe Hall in the County of Dorset died the 25th May 1830 Aged 46 Years*. Thus, it is evident from these matching inscriptions that headstone 130 had originally marked grave 888, and that after falling over, this headstone had not moved far from its original position.

#### *Recumbent headstone 135*

Similarly, recumbent headstone 135 overlay two burials (950 and 954). The inscription on the headstone (which reads: *Sacred to the memory of Mrs Ann Richardo wife of Mr. Benjamin Richardo of Winfor Terrace City Road died 27th December 1814 in the 28th Year of her life*) matched the breastplate of Ann Richards (died 27/12/1814, aged 28 years). She was buried alongside a newborn infant (954), whose existence was not mentioned on the headstone.

#### *Recumbent headstone 156*

Recumbent headstone 156 was found overlying the graves of 874 and 875, both unnamed individuals; a child of 3-7 years and a mature female. These could not be

matched confidently to the names inscribed on the inscription on the headstone, which read as follows:

*Sacred to the memory of Mr Deskford Grant 15 years an inhabitant of this parish eldest son of the Revd Robert Grant minister in Cullen, North Britain who died on the 3rd July 1820 Aged 65. He was a man of the strictest integrity and a sincere friend. Also Mrs Elizabeth Mahat.....e sister of the above who departed this life on the 12th day of September 1840 aged 69.*

#### *Recumbent headstone 155*

A recumbent headstone was found close to two burials 1165 and 1166. The inscription read as follows: *To the memory of Mrs Ann Tadwell wife of Mr Henry Tadwell of this parish who died June 8th 1780 Aged 42 Years. Also the above Mr Henry Tadwell who died Jan 5th 1806 Aged 59 Years.* Because neither of the burials were named, it was impossible to find a relationship between these burials and the headstone. The skeletons were of a young and an older male. This also makes an association doubtful.

#### *Recumbent headstone 238*

The inscription on headstone 238 read as follows:

*In memory of Mrs Johannah Watts, who died 6 Jan 1810 Aged 73 Years. Roseanna Chislett daughter of the above and wife of Isaac Chislett....died April 4th 1825 Aged 20 Years. Eleanor Chislett died April 4th 1832 Aged 57 Years. Isaac Chislett died Feb 12th 1851 Aged 76 Years.*

Headstone 238 was found overlying a grave group of six individuals (817; 820-824). None could be named conclusively from *departum* plate inscriptions, but two breastplates suggest that this burial group may be the Chislett family, albeit not those individuals mentioned on the headstone. The breastplate of an adult female (820) reads: *Mr.....horean Ch..... died 26 November 1812.* The breastplate from burial 821 reads: *..... Sarah Chis-l.... died 11 November 1818 aged 72 years.* It is possible that burial 820 and 821 were earlier Chisletts buried in this family plot before the above-mentioned family was put to rest here.

## The Church

The church was built 1722-23 to designs by two of the Fifty New Churches Act surveyors, John James and Nicholas Hawksmoor. The church was redundant by 1960, unroofed by the Church Commissioners, leaving only the spire and the walls, and left derelict after no buyers emerged. Nothing came of successive plans for conversion and the shell of the building was eventually consolidated as a ruin in 1994 (Cherry and Pevsner 1998, 604). The organ case went to St Giles Cripplegate, reredos and altar rails to the north-west chapel at St Andrew, Holborn. The body of the church is of stone with a Venetian window in the east wall. The western tower has a spire as its fluted obelisk. The west tower rises from the ground and the aisle roofs form a fragmentary pediment a little behind its front. The west entrance in the tower is flanked by staircase wings with north and south doorways, an oculus over each entrance, domed vestibule beneath the tower, and flanked lobbies each with an elegantly cantilevered stone stair in a curved end. The interior had tall unfluted Ionic columns, a shallow vault to the nave and transverse vaults to the aisles with galleries on three sides.

George Dance the Elder was a member of the vestry and the church has often been erroneously attributed to him (Weinreb and Hibbert 1983, 752). He was buried here in 1768, and in 1788 his children provided a black marble slab which has since been removed or destroyed. The type founders, William Caslon, father and son, were buried in the southern churchyard in 1766 and 1778 respectively.

### *Crypt development*

The crypt comprises four west-east aligned barrel vaulted bays built in red brick. There are three spine walls each one with three vaulted openings in line with other openings. Two outer spine walls (between Bays 1 and 2, and Bays 3 and 4) are buttressed by primary buttresses (0.36 m deep). Some of these appear to have been removed and those at the south-east corner of the building were replaced/enveloped by larger modern brick buttresses. The primary mortar is soft and white. Scars visible in bays 2-4 (repaired in moderate hard, grey cement mortar) suggest that the crypt was constructed in three sections east-west. The crypt walls comprise alternate courses of headers and stretchers. Above the level of springing, the brickwork of the crypt abuts

the brickwork of the piers supporting the ground level arcades. There are access arches between the bays.

Bays 2-4 were all used for burial and consequently the floor level was significantly higher (c 1 m). These bays contain many individual 'family' vaults apparently all early-mid 19th (as suggested by name plates and memorials).

Bay 1 appears never to have been used for burial. A test pit excavated at the western end to a depth of 0.56 m below the (presumably inserted) concrete slab found no evidence for burial. Bay 1 is decorated with painted plaster with a red coloured dado section. This extended over secondary inserted blocking brickwork between bays indicating a later date. Electric lighting etc may have been inserted at this time. A vent (27) in the south wall of the church allows air into bay 1. It appears to be part of the primary structure and measures 0.75 x 0.62 x 0.50 m. Presumably, originally there would have been a grille over the top.

The crypt covers an area of approximately 430 m<sup>2</sup>, the floor level being at 17.58 m OD. It was sealed for safety reasons some time before 1996. Observations carried out by Dr Susan Young and Simon Coe within the crypt before it was sealed suggested that an amount of vandalism had taken place and that some of the burials had been disturbed. This was confirmed by archaeological investigation.

The floor of the crypt would have been earth, and burials did take place below floor level. In August 1964, instructions were received from the London Diocese to remedy damage and secure coffins after disturbance caused by people entering the crypt. It was intended to place them at the east end of the crypt and seal the openings with brickwork. The London Necropolis Company was to be employed in resealing and casing the human remains and handling the coffins to be moved.

Much of the crypt had been backfilled with earth, all the coffins being covered. It was suggested by Simon Coe that much of the spoil in the crypt derived from the clearance of the churchyard area north of Mitchell Street in 1937, and that human remains from that site were therefore included among it.

### *Vaults within the crypt*

There were 21 vaults within the crypt of St. Luke's, containing a total of 72 burials, 56 of which were named individuals. Within the bays of the crypt beneath the church, much of the internal space of the crypt was divided off by brick walls or iron railings

to create small rectangular private family vaults. There were six of these structures in Bay 1, four in Bay 2, ten in Bay 3 and one large vault in Bay 4.

The vaults were first used in 1756, with the interment of William Wood (vault 251). The last to be buried was Charles Stoke (vault 15) in 1853. From evidence of named individuals it would appear that very few individuals were interred before 1800 or after 1850, the peak period of burial being between 1831 to 1840 (Figures 3.1 and 3.2). There is considerable variation in the length of time that each vault was used. Vault 251, the Wood family vault, was utilized for 64 years, whilst others, such as Vaults 11, 13 and 24 contained only single coffins. The number of coffins per vault ranged from single interments to as many as 11. From inscriptions it is apparent that these represented up to three generations of a family.

#### *Bay 1*

##### Vault 240

Rectangular vault in the eastern half of Bay 1, abutting the northern bay wall. The vault is defined by iron railings, with 'spear' tops, set into stone kerbs (which project 0.03 m above floor level of vault). Corner rails are set into the roof of the crypt, and railing is shaped to follow the curvature of the crypt roof. During modern refurbishment, this structure was encased within a later modern breeze block wall.

The front railings hold a door with two locks. An iron inscription plate on the door reads; *The Family Vault of John Gardner, City Road*. Dimensions of vault: 2.2 m x 1.6 m. Contained coffins 725; 726; 727; 728; 762; 763 and 764.

##### Vault 251

Vault at the eastern end of Bay 1 against the eastern and southern walls of crypt. Constructed of brick and hard grey mortar with lime inclusions. Original arched entrance in west facing wall blocked by later brickwork. Brick floor raised above level of the crypt floor. Small stone plaque on northern wall of vault reads *W. Woods, Gent 1756*. Contained coffins 253; 254; 255; 493; 494 and 495.

##### Vault 470

Vault located at the eastern end of Bay 1, abutting the eastern and northern walls of the crypt. Originally the vault appeared to have been defined by an iron railing structure. During modern refurbishment, the vault was enclosed within a breeze block wall and a raised cement slab. Steps led up to a raised window or vent. Below the slab, four lead coffins were visible. These rested on the brick floor, and were covered

by spoil. The brick floor was raised by 0.4 m above the level of the crypt floor. Dimensions of vault: 2.5 m x 2.3 m. Contained coffins 471; 472; 473 and 474.

#### Bay 2

##### Vault 14

Rectangular vault located at the western end of Bay 2, adjacent to Vault 15. Composed of brick bonded with medium hard white mortar. Doorway (1.84 m x 0.91 m) set into eastern wall. Door has since been removed, but the latch in its iron frame remains *in situ*. The door frame is decorated with vertical twirls in head.

Stone lintel inscribed with *Charles Overton*. Vault was empty.

##### Vault 15

Rectangular vault located at the western end of Bay 2. Large opening (1.06 m wide) created in eastern wall. Walls rise to barrel vault. Small decorative 'vent' found above opening, and above stone memorial plaque. Plaque inscription reads: *The family vault of Thomas Hughes 1818*. Contained coffins 305; 306; 307; 308; 342; 343 and 344.

##### Vault 24

Small vault located at the eastern end of Bay 2. Constructed of brick, bonded with medium-soft grey mortar. A wooden door was found lying on the floor, and appeared to have collapsed directly from the existing vault opening. Condition poor with little of the structure surviving. Contained coffin 1196.

##### Vault 25

Vault in the eastern half of Bay 2, abutting the northern wall of the bay. Constructed of yellow brick bonded with fairly hard, white mortar. An iron barred gate in situ in the eastern wall is composed of eight vertical bars, six innermost circular section bars and three horizontals. A stone lintel over the gate is inscribed: *The family vault of Thomas Dalton esq.* On the south-facing wall is a stone memorial (0.68 m x 1.06 m) inscribed with *Thomas Dalton esq. died December 3rd 1846 in his 85th year. Elizabeth Harrison grand-niece of the above died November 17th 1852 in her 42nd year*. Contained coffins 770 and 771.

##### Vault 26

Vault located against eastern wall of crypt, adjacent to Vault 24. Constructed of brick bonded with medium-hard white mortar. Timber lintel forms western opening to vault. Lintel supports many bricks, straining somewhat under the load. Vent on south side, just below the main barrel vault, is composed of four rectangular openings. There is a large space for a stone plaque above the openings. An inscribed stone

plaque, found on the floor, matches the dimensions (0.76 m x 0.59 m) of the empty space, and belongs to this vault. Inscription reads: *Within this vault lies the body of William Dore Obit Oct 21 1816 aged 32. Mary Dore Obit May 6 1817 aged 4 years. Mary Dore Obit Jan 8 1821 aged 40 years.* Contained coffins 840; 841; 842 and 843.

### Bay 3

#### Vault 11

Small vault of simple rectangular plan located towards the western end of Bay 3, abutting northern wall of bay. Constructed of brick bonded with hard, grey, grainy mortar. Inner faces rendered. Iron straps tie the wall to the primary buttress. The structure has almost totally come away from the primary wall of the crypt. The vault has been broken open at the western end, above the memorial stone.

Memorial stone is inscribed with *Matthew Little, died 3rd March 1808 aged 6 months.* Contained coffin 337.

#### Vault 12

Vault of simple rectangular plan, located at the western end of Bay 3, adjacent to Vault 13. Constructed of brick bonded with medium-hard white mortar. Large opening in eastern face appears once to have held a memorial stone, which is no longer *in situ*. A stone lintel is positioned above former memorial, and a timber lintel is immediately behind it. Contained coffins 301; 302; 303; 304 and 361.

#### Vault 13

Sealed vault located at the western end of Bay 3, adjacent to Vault 12. Constructed of red brick bonded with medium-soft white mortar. Large memorial stone (1.7 m x 0.9 m) set in wall, reads *M. Bowes Todd, late of ? Firshurn Place who departed this life Aug 8 1800 aged 32 years.* Address is not very clear. Single coffin rests on two brick row runners with a timber at each end. An oval glass viewing window with a black metal and gilt border is present. Contained coffin 350.

#### Vault 16

Vault located towards the western end of Bay 3 on the southern side. Constructed of white painted brick, inside and out, bonded with medium-hard white mortar. The vault has not been built or tied into the crypt wall or ceiling, but butts the main structure. Door opening (1.6 m x 0.95 m) in western wall with iron grille door *in situ*. Door is composed of a frame in-filled by five vertical bars topped with 'spear' tops. Stone lintel positioned above the doorway. Copper plate on door is inscribed: *Family*

*vault of George Hathorn Esq, Brunswick South.* Two timber runners have been placed on brick floor. Contained coffins 362; 363; 364; 465 and 466.

#### Vault 17

Former vault located in the western half of Bay 3 abutting the northern wall of the bay. Adjacent to Vault 18. Now demolished to ground level. Appeared to have been composed of a single skin of brick, bonded with hard white mortar. Brickwork painted on the outward face only, suggesting that painting took place after vault construction. Contained coffins 339; 340 and 341.

#### Vault 18

Rectangular vault located in centre of Bay 3 abutting the northern wall. Constructed of brick and medium-hard white mortar. The vault is composed of three free-standing walls, attached to the original bay structure by one square iron section bar at the western end of vault. Part of the original support pillar of the crypt and the eastern entrance to Bay 4 was cut away during the vault construction. Eastern and western walls are one brick thick, whilst the southern wall is two. Eastern doorway (0.91 m x 1.36 m) is surmounted by stone lintel, and sealed by an iron door, which remains *in situ*, but is off its hinges. Stone lintel inscription reads: *Mr W. Sutton's vault 1831.* Contained coffins 716 and 717.

#### Vault 19

Private vault located in the centre of Bay 3, and abutting its northern wall. Constructed of white-painted brick bonded with white medium-soft mortar. Building of vault involved the removal of crypt support to four courses high. Vault remains sealed, although a number of bricks have come away at the eastern end, and subsidence has caused large cracks. Stone lintel in western face is located immediately above memorial, and straight joints are located either side of this (ie. a second body was added after initial construction). Inscription on lintel reads: *The private vault of Rev. Trefusis Lovell, rector of this parish, in which are deposited the mortal remains of Margaret, his beloved, virtuous, lamented wife, who died on Sunday June 25th 1837 aged 64 years. Also to the memory of the Re. Trefussis Lovell M.A. for upwards of 30 years rector of this parish; and formerly arch-deacon of Derry, Ireland, who departed this life October 10th 1841 in the 78th year of his age.* Contained coffins 855 and 856.

#### Vault 20

Rectangular private vault located in the eastern half of Bay 3, abutting the northern wall of the bay. Constructed of yellow brick, unpainted externally. Internally, the two secondary walls appear to contain faint traces of paint, but this may just be discolouration or staining. Primary arched wall is plastered, possibly to conceal the removal of some of the original crypt pillar support in the dividing wall between Bays 3 and 4. Inscription on the stone plaque (1.05 x 0.63 m) on the southern wall reads: *Mrs Mary Ann Robinson wife of Mr E Robinson died the 5th of May 1838 in her 40th year.* The lower two-thirds of the slab is blank. Contained coffins 972 and 973.

#### Vault 22

Rectangular vault located at the eastern end of Bay 3, adjacent to Vault 21. Constructed of brick bonded with medium hard white mortar. Timber door-frame (0.95 m wide) in the western wall, but no door or memorial in situ. A timber bearer is set into the northern wall of vault, 1.1 m above the current floor level. Contained coffins 980; 981; 982; 983; 987 and 988.

#### Vault 23

Rectangular vault located in the eastern half of Bay 3, abutting the southern wall of the crypt. Constructed of whitewashed brick bonded with fairly hard white mortar. Access to the vault would have been at the eastern end, where there is a stone lintel, 1.26 m above the level of the present floor, straight joists on either side, and bricks similar on either side of the joint. Stone memorial plaque in the northern face reads: *John Capron of Finsbury Square died 18th May 1833 aged 78 years.* Lower half of plaque is blank. Contained coffin 492.

#### Bay 4

##### Vault 8

Large vault was located at the eastern end of Bay 4. Constructed of white-painted brick bonded with medium soft white mortar. It clearly abutted the barrel vault of the crypt, and was slightly coming away from the wall in places. Southern western wall was angled outwards so as to avoid blockage of the eastern entrance to Bay 3 (now blocked). Northern western wall was aligned at right angles to the spine of the crypt. This abutted a possibly blocked entranceway in the northern wall. In the eastern wall, within the crypt, a circular opening (very similar to one found at the eastern end of Bay 1) had been blocked with modern brick and mortar. Iron lining encircling inner face of the opening was still *in situ*. No memorial or inscription survived, but

stylistically this feature may have dated to the early 19th century. Two projecting entrance piers in western wall contained a wrought iron grill consisting of vertical circular section bars and four horizontals. Five horizontals were removed in the past. Contained coffins 1218; 1219; 1220; 1221; 1222; 1223; 1257; 1258; 1259; 1260 and 1261.

## Discussion

The greater popularity of burial within the crypt of St Luke's church does not appear to have developed as a practical solution to burial overcrowding in the churchyards. From the plans of the two churchyards, it is evident that throughout its use as a place of burial, there was always considerable space available for the erection of additional vaults and shaft graves, and for burial within more humble earth-cut graves. Rather, the popularity of crypt burial appears to be ideological, based on the belief that greater worldly and/or spiritual benefit would be derived from interment there.

The period of burial at St Luke's Church coincides with the rapid urban expansion of London in this period (Porter 2000, 248). It also predates the emergence of municipal cemeteries, such as Kensal Green and Highgate, and legislation outlawing interment in the overcrowded churchyards of cities in the 1850s (*ibid*, 331; Curl 2002, 135). Originally established to address the urgent problem of severe over-utilisation of churchyards for the burial in this period, urban cemeteries rapidly became a fashionable new venue for the display of status through burial ritual (Curl 2002, 206-244). It is thus unsurprising that burial at St Luke's became less popular from this time onwards. Officially, it stopped altogether in 1853. The Vestry minutes record that a petition for an extension of time for closure of the churchyard and crypt to further burial had been turned down by the then prime minister, Lord Palmerston. At the end of that year, burial was discontinued, and the vaults sealed (MoLAS 1996).

Like the crypt vault burials, the churchyard vaults and shaft graves contained small family groups. Vault 1 was found empty, and vault 174 contained only a single coffin. However, all other shaft graves and vaults contained between two and nine individuals. On average, these churchyard structures held 3.6 burials. This is broadly similar to the mean of 3.43 interments per vault found within the crypt. However, there were considerably more named individuals identified within the crypt vaults (mean of 2.67) than in the churchyard vaults and shaft graves (mean of 1.57). This

probably reflects the better preservation and retrieval of coffin plates within the crypt vaults.

## CHAPTER 4 BURIAL PRACTICE AND MATERIAL CULTURE

*by Ceridwen Boston and Angela Boyle*

### Coffins and coffin fittings

#### *Historical background*

By 1700-20 the funeral furnishing trade was a firmly established business, providing fittings for all classes of people and at various costs, depending on the status and wealth of the deceased (Litten 1991). The financial investment in funerary panoply grew over the course of the 18th century and into the 19th century, reaching its zenith in the 1840s. Even amongst the poor the importance of providing a decent burial was keenly felt. However, for those that could afford it, the coffin itself was just one aspect of the elaborate mourning and funerary practices surrounding the death of a loved one in this period. Funerals of the wealthy frequently involved processions of black draped hearses, black plumed horses, mutes and chief mourners, a complex symbolism surrounding appropriate mourning dress, grand memorials, and of course the heavily decorated coffin itself. Rigid mores surrounded the conduct of the surviving members of a family, and prescriptions on the correct social behaviour and dress of mourners was assiduously adhered to, often for years following the death of a loved one.

However, after the 1840s, public sentiment changed yet again. Increasingly, such effusive displays of mourning were seen to be excessive and undesirable. In particular, elaborate, expensive funerals began to be regarded as vulgar, ostentatious displays of wealth and status, and increasingly, were considered to be in poor taste. In this period many caricatures stigmatise undertakers as avaricious, preying on the vulnerability of families in grief, exploiting other peoples' misfortune and their desire to be seen to 'do the right thing' by the dead. Over the middle and later Victorian period a taste for simpler funerals became the norm, and this persists today. Interestingly, in the further reaches of the old British Empire elements of the earlier burial traditions persist. Coffin fittings very much in the elaborate early Victorian mode were being manufactured in Birmingham and shipped out to the Caribbean (particularly to Jamaica) as recently as the 1960s. The coffins from St Luke's Church

date mainly to the heyday of the late Georgian/ early Victorian<sup>2</sup> funerary tradition at its most extravagant.

### *Early 19th-century perceptions of death*

Social historians have often accused the Victorians of a morbid and unhealthy obsession with death. What is clear is that this rite of passage was celebrated more by the Victorians than in any preceding periods, in terms of preparation for death, funeral ritual, and the long period of mourning that followed. Victorian deathbed scenes, as depicted in the literature and art of the day, may seem to modern eyes morbid or mawkishly sentimental, but they represent a genuine attempt to confront the awful reality of death, such that when one's time came death could be met with serenity and calm resignation. In a society where the infant mortality rate varied between 20-50% (Rugg 1999), where epidemic infections could sweep through cities with terrifying ease and where medical interventions were still rudimentary and powerless to halt the advance of many diseases (such as tuberculosis), death was a familiar part of life. Rather than deny the very real presence of death in everyday life, the Victorians chose to accept and celebrate it, to give it centre stage. Instead of a morbid fixation, this response may be seen as a very human, understandable, and often very therapeutic confrontation of humanity's deepest fear.

Rugg (1999) writes that this Victorian concept of a 'good death', a death faced with equanimity, came about through a number of ideological and medical developments in the early years of the 19th century. Advances in medical knowledge and a more widespread trust placed in the medical profession lead to a transformation of the deathbed experience, the doctor's presence playing as central a role in the proceedings as the cleric. A heavy reliance on opiates to ease the pain of the dying served to disarm death of much of its terror. Instead of the emphasis on the physical torments of death and the spiritual torments of hell that had so dominated the thinking of earlier generations, the later Georgians and early Victorians were now more able to perceive death as a gentle slipping away, a falling asleep. Christian teaching also changed emphasis in this period. God became much more a God of Love than a God of Vengeance, and instead of hellfire and eternal damnation a gentler concept of the afterlife as heavenly and eternal rest developed. Considerable emphasis was placed on

---

<sup>2</sup> The Georgian period (1714-1837); the Victorian period (1837-1901)

heavenly reunion with loved ones in the afterlife, and was a great source of comfort to the bereaved. The effects of the Romantic movement also had a profound effect on attitudes to death and grieving. The movement's emphasis on individualism and the expression of sentiment made the outward displays of grief more socially acceptable, even desirable, both in an emotional and in a material sense.

The material culture surrounding death and mourning was particularly rich in the 19th century. Memorials to the dead abounded in many forms. For example, it was common practice to draw or paint the dead or dying, and later in the period, to photograph the corpse. Death masks were sometimes taken of the face or hands of the dead. Two examples of such effigies were found in a child's coffin at St George's Church, Bloomsbury (Boyle *et al.* in prep.). Locks of hair were often collected as keepsakes, or converted into jewellery.

Correct mourning dress was rigidly prescribed, and individuals failing to adhere to social conventions risked social ostracism. The period of mourning varied with the closeness of the relationship. Widows were expected to be in deep mourning for a year and a day following the death of their husband, wearing only dull lack-lustre fabrics such as crepe or bombazine. After this they might wear more lustrous fabrics, such as black silk. After two years the widow might go into half-mourning when she was permitted to wear purple or mauve. In addition to prescriptions on dress, the social behaviour of the bereaved was rigidly laid out. For example, a widow might not attend public functions, and was prohibited from re-marriage for a year following the death of her husband. By contrast a widower could remarry as soon as he pleased, but his new wife was expected to go into mourning for her predecessor (May 2000).

Social display of mourning manifested strongly in funerary ritual, and proved an admirable medium through which the social prominence of the deceased and family could be displayed. The necessity of giving a good 'send-off' to a loved one was felt by all classes of society. Failure to do this reflected on an individual's very respectability, and many poorer individuals beggared themselves in the attempt to put on a decent funerary spectacle (May 2000). The coffins from the churchyard graves and crypt interments at St Luke's Church show great variation in the richness of their fittings, reflecting the deeply entrenched social stratification that characterised this society. Whilst some could only afford simple wooden coffins, the opportunity for social display was not missed by the middle and professional classes interred in the

extramural vaults and crypt of St Luke's Church. May (2000) estimates that the average amount spent on a funeral of this social class was in the region of £100, notwithstanding the cost of interment in the vaults or crypt (see Chapter 2 above for details of burial fees). The richness of the coffins found within the crypt is eloquent testimony of the social ambitions of this class.

### *Coffin construction and materials*

Coffins used in the later post-medieval period were of the flat lidded single-break type (Reeve and Adams 1993, fig. 51 shows an exploded view of a single-break coffin), and the coffins found at St Luke's Church were no exception. Coffins varied in construction and material, from the most simple unadorned wooden coffins found in pauper funerals to triple layered affairs of wood-lead-wood, heavily adorned with velvet and elaborate metal fittings. The most simple coffins were constructed of a single layer of wood nailed together with iron nails at the corners and along the coffin length. More elaborate wooden coffin constructions were double layered, or possessed a double lid. Some lids were especially designed to foil attempts by 'resurrectionists' or body snatchers to open the coffin and steal the corpse for later sale to anatomy schools for dissection (Litten 1991). On the 30th November 1758 the Vestry Minutes recorded that 'a reward of £5 be given to any person or persons who shall at any time detect and apprehend any person stealing a Corps out of any of the Burial Grounds belonging to the church, to be paid upon conviction thereof by the churchwardens.' The wooden coffin may or may not have been upholstered and decorated with metal coffin fittings, depending on the wealth and inclination of the mourners.

More expensive coffins possessed a lead shell in which the body was encased. Lead lined coffins are most commonly used for interments in the crypts of churches and within intra- and extra-mural vaults and brick-lined shaft graves. The lead of these coffins or shells served to slow, and sometimes arrest the decay of the corpse. The Georgian/Victorian religious belief in the importance of the integrity of the physical body on the Day of Judgement underlay some of the motivations to halt the natural corruption of the corpse. It also fed into the gentle, romantic metaphor of death as eternal rest, underplaying the processes of physical decay that had so pre-occupied people of the later medieval and earlier post-medieval periods (Rugg 1999). On a practical level, the containment of body liquor within a water and air-proof container was of particular importance when interring individuals within the church

vaults or beneath the floor of the church itself. In many churches, such as St George's, Bloomsbury (Boyle *et al.* in prep.), encasement within a lead shell was a basic requirement of interment within the church crypt. The legal imposition of lead coffins for intramural burial occurred in 1815. Previously on the 12th October 1810 the Vestry Minutes recorded 'that hereafter no corpse be permitted to be placed in the vaults except in leaden or metal coffins.'

Lead-lined coffins were either double or triple layered. Double-layered coffins were composed of a lead shell either enclosed by, or enclosing a wooden coffin. Triple-shelled coffins had a wooden inner coffin within a lead shell, the lead itself being enclosed within an ornately decorated and upholstered wooden outer case.

Triple-shelled coffins represent a great investment in time, materials and money, and as such, indicate the wealth of the individual interred and/or the surviving family. The inner wooden coffin was usually of elm, particularly favoured for being more impermeable to water than many other available woods. Planed elm planks were glued and screwed together, and the seams caulked with Swedish pitch. The interior of the coffin was usually lined with fabric, most commonly cambric, a fine white linen made in Cambray, Flanders (Litten 1991). The inner wooden coffin was then encased within a lead shell. The fashioning of the lead shell was beyond the capabilities of most coffin makers, and usually undertaken by a local plumber (*ibid*). Unlike the inner or outer coffins, the lead shell had to be bespoke. Lead sheets were cut and shaped around the inner wooden coffin. The pieces of lead were then soldered together to create a water and airtight container. Then, either an inscription was engraved directly onto the lead shell, or a fairly plain lead inner coffin breastplate was soldered or riveted thereon. The outer wooden case was prepared and covered with upholstery and decorated with iron or brass studs in advance of the placement of the lead shell within it. Lowering the lead coffin into the outer wooden coffin or case was a difficult and delicate business, usually requiring six men to lift the shell by means of lengths of webbing. This webbing was then cut and removed from beneath the lead shell, and the lid of the outer wooden coffin was screwed or bolted into place (*ibid*).

#### *Lining of the inner wooden coffin*

Cambric was widely used to line the interior of the inner wooden coffin. Often a decorative frill of punched 'lace' covered the coffin sides. This was aesthetically most important where the corpse was to be viewed prior to burial. Fragments of this coffin lining were found adhering to the internal wood of many of the coffins at St Luke's.

Fragments of cambric with a punched lace frill were found within inner wooden coffin 213 (vault 109), coffins 981 and 982 (vault 22); 990; 1039; coffin 1149 (vault 1160), 1151 and 1207. Coffin 307 (vault 15) was more exotic, being lined with a very fine black silk.

Traditionally, the base of the inner coffin was covered with a shallow calico-covered layer of sawdust or bran, which helped to absorb some of the body fluids released during putrefaction. It was observed at St Luke's Church, St George's Church, Bloomsbury (Boyle *et al.* in prep) and St Nicholas' Church, Sevenoaks (Boyle pers. comm.), that plentiful sawdust or bran within the coffin correlated closely with poorer preservation of the skeleton. This is probably the result of leaching of the inorganic bone minerals due to the more acidic environment created by the decaying bran or sawdust (Janaway 1996).

As an alternative to this sawdust or bran layer, the corpse was sometimes laid out on a mattress, with a pillow beneath the head (Litten 1991). This practice reflects the strong symbolic association between death and sleep that developed in the later Georgian/Victorian mind during this period (Rugg 1999). At St Luke's, six such mattresses were found. Coffins 364 (vault 16) and 923 each contained a horsehair mattress, and coffins 926 and 990 (vault 21) a kapok-stuffed mattress and pillow. Kapok is a fine short-stapled cotton wool, also known as silk alton. The material of the mattress within coffin 1270 was not identified. The mattress within coffin 307 (vault 15) was most elaborate, the kapok-stuffed mattress being covered with silk and decorated with tassels. The skull was found resting on a horsehair pillow. Another pillow was found beneath the bonneted head of a Mrs Elizabeth Burnill (coffin 491; vault 483).

One curious and highly unusual find within one coffin (1258) at St Luke's Church was a large quantity of liquid mercury on the coffin base. The reason for its presence in the coffin is not well understood. Mercury was used as a treatment for syphilis and it has been suggested that this treatment may in some way explains its presence within the coffin. No evidence for the disease was found on the skeleton of this young man of 19 years. However, tertiary syphilis is only detected on the skeleton in 10% of cases (Roberts and Manchester 1995). Thus, it is quite possible that he did have the disease although it had not manifested osteologically. His age certainly, suggests someone too old to have been suffering from congenital syphilis, but not too young for the sexually transmitted equivalent to have developed sufficiently for the

disease to be clinically recognised. It is thought by some that the poet and forger Thomas Chatterton who died at the age of 17 years in 1770 from arsenic poisoning may have been trying to cure himself of venereal disease. An alternative hypothesis is that the mercury was placed within the coffin as a means of preserving the corpse. Mercury, like lead, is toxic to many bacteria, and consequently slows the process of natural decay of the body.

### *Coffin fittings*

From the early 18th century, it became the norm to decorate the upholstery of the outer wooden case with a suite of metal coffin fittings or furnishings. The number and materials used for the fittings reflected the wealth and hence, status, of the deceased and family. Considerable variation may be observed across the classes of Victorian society. However, it is important to bear in mind that even the more humble went to considerable pains to bury their loved one with as many accoutrements as they could afford.

A full suite of coffin fittings was composed of one to four *departum* plates (an inner and outer breastplate, a headplate and a footplate), lid motifs, escutcheons, grips and grip plates. In addition, brass or iron studs, originally used to secure the upholstery to the wooden case, became a decorative device, being arranged to create complex patterns on the lid and side panels of the coffin.

Grips were produced by casting. All other coffin fittings were stamped using dies (Litten 1991). Between 1720-30 these were produced by hand-operated die stamping machines, but after this such machines became power-assisted (ibid). Coffin fittings could then be produced *en masse* and were financially accessible to a wider audience by the mid- to late Georgian period. Excavations of the 18th- and 19th-century churchyard and crypt of Christ Church, Spitalfields, London, undertaken in the 1980s, revealed a large number of coffin fittings. The taxonomy compiled from these fittings (Reeves and Adams 1993) forms the basis for identification of the styles in vogue throughout this period.

In comparing the dates for the fittings from St Luke's Church with those from other sites, it is hoped that more refined dating of coffin fittings styles will be possible. In addition to comparisons with Christ Church, Spitalfields, fittings from St Luke's were compared with fittings from St George's, Bloomsbury (Boyle *et al* in prep), and St Bartholomew, Penn, Wolverhampton (Boyle 2004), two broadly

contemporary burial sites recently excavated by Oxford Archaeology. Table 4.1 summarises the results of this comparison. Styles from Christ Church, Spitalfields, are prefixed in the text by the abbreviation CCS; new styles identified from St Luke's Church, Islington are prefixed by OLR; those from St George's church, Bloomsbury, are prefixed by BBM.

New coffin fitting styles from these new sites have been added to types known from Christ Church, Spitalfields, to create a more accurate and comprehensive 'master catalogue' that may be used in future burial recording of this period. Archaeological research into Georgian/Victorian funerary regalia is in its infancy. Data from sites such as St Luke's Church are therefore vital in enriching our understanding of the material culture of the Victorian funeral, and through this, to provide insights into perceptions of death and resurrection in the 18th and 19th centuries.

*Table 4.1 New types of coffin fittings from the churches of St. George's, Bloomsbury, and St. Luke's, Islington, that could be matched stylistically, but did not match the Christ Church, Spitalfields taxonomy. OLR refers to new styles from St Luke's church, whilst BBM refers to new styles from St George's.*

Matching Coffin Fittings from St Luke's church, Islington, and St George's church, Bloomsbury

A large number of matches were found between coffin fittings from St Luke's church and Christ Church, Spitalfields (Table 4.7). In addition, 67 hitherto unknown styles

were identified. These were drawn on site and the illustrations are included in the report (Figures 4.1-4.73).

#### *Symbolism of motifs used on coffin fittings*

This section is largely based on information from [www.vintageviews.org/vv-tl/pages/Cem-Symbolism.htm](http://www.vintageviews.org/vv-tl/pages/Cem-Symbolism.htm). The motifs displayed on coffin fittings were not merely decorative, but were deeply imbued with symbolism. Many represented Christian symbols of death, eternal life and resurrection, whilst others owe more to secular symbolism. Classical symbolism abounded, the urn (an Ancient Greek symbol of mourning) was a very popular motif well into the 1850s. Some motifs refer to the age or unexpectedness of the death of a particular individual. For example, the broken column (as seen in the *resurgam* lid motif OLR 4) denotes untimely or unexpected death, a life cut short prematurely. Cherubim were particularly favoured for the coffins of infants and children. Composite symbolism was often used. For example, lid motifs OLR 1-3 of flaming urns cloaked in drapery and laurel wreathes combine the symbolism of drapery and the urn as symbols of mourning, the flame as the flame of eternal life, and the laurel wreath as victory over death (Figures 4.70-72).

Angels and cherubim are very popular motifs on all types of coffin fittings at St Luke's Church. Angels obviously denote heaven and the afterlife, but a cherub's head without a body symbolises the soul. Angels blowing trumpets represent God's glory and victory over death, or alternatively the Day of Judgement. A few of the most common motifs and their symbolism in a Victorian burial context are listed below:

- Shells - fertility, resurrection and pilgrimage (particularly the scallop shell)
- Sunbursts- renewed life after death
- Crown- the crown of Jesus, immortality, righteousness, glory of eternal life
- Flame- eternal life
- Scroll- life and the passing of time
- Skull- death and mortality
- Winged face- the departing soul

Flowers have long played a symbolic role in funerals, the colour and species conveying complex ideas about life, death and rebirth. In the early Victorian period, the placement of wreaths of flowers on the coffin was largely confined to the funerals of girls and young maidens. Evergreens and white flowers, such as roses or lilies,

were acceptable. Bright colours were frowned upon, and even the stamens of white lilies were cut off lest the golden pollen affect the effect of purity (May 2000). Over the course of the 19th century, the laying of wreathes on the coffin and on the grave became more widespread across society (Cox 1998c, 116; Mays 2000). At St Luke's Church, an arrangement of flowers had survived on top of a coffin of an unnamed young female (coffin 188). Examples were also recorded at St Nicholas, Sevenoaks (Boyle 1998).

Breastplates and grip plates are particularly rich in foliage and floral motifs. Whilst the majority are stylised or generic plants, occasionally it is possible to recognise the species. Lilies and chrysanthemums have long been associated with death. Lilies are particularly associated with the Virgin Mary and were most commonly associated with the burial of women. The lily was often seen to represent purity, resurrection and the restoration of innocence of the soul at death. Roses are frequently depicted on breastplates. Roses represent beauty, hope and unfailing love. Depending on the stage of their opening, the rose may represent the age of the person at the time of their death, a bud denoting a child, a partial bloom a teenager, and a rose in full bloom, an adult. Other plant motifs depicted on the fittings from St Luke's Church are listed below:

- Acanthus leaves- heavenly garden
- Daisy- childhood innocence, youth, Jesus the Infant
- Fleur-de-lis- flame, passion, love of a mother
- Laurel- distinction in life, victory over death
- Oak- stability, strength, honour, eternity, the cross of Jesus, liberty
- Palm- spiritual victory over evil, success, eternal peace, Jesus' victory over death
- Poppy- peace, sleep (and hence, death), consolation
- Thistle- earthly sorrow, Christ's crown of thorns, Scotland as country of origin

#### *Upholstery and stud-work*

In the later post-medieval period, the outer wooden coffin was usually upholstered in either velvet or baize, the former being the more expensive alternative (Litten 1991). At St Luke's Church, the preservation of upholstery fabric was very poor, with only 33 coffins retaining vestiges of recognisable textile on the outer wooden coffin. Of these, 28 were of baize, and 2 of velvet. On three coffins a loosely woven, coarse

fabric was identified. This was probably shoddy, rough cloth made of woollen yarn, obtained by tearing to shreds refuse woollen rags, and by the addition of some new wool. Shoddy was often used as a backing for velvet upholstery, which, presumably, had since decayed. Traditionally, the colour of coffin upholstery was black, but coloured cloth did begin to be used in the early 19th century (Litten 1991). At St Luke's Church, two coffins displayed coloured upholstery: coffin 158 was covered with yellow fabric, and coffin 188 with green.

Upholstery studs were composed exclusively of brass or of iron. Of the 123 coffins with extant studs 82 were composed of iron, and 41 of brass (Table 4.2). In a number of cases these were painted black, and in one case the brass studs had been gilded. Due to the poor preservation of the outer wooden coffins little of the decorative arrangement of the studs could be identified. Indeed, in the vast majority of cases only single loose studs or short rows of 3-10 studs were recovered from the grave backfill. Only two coffins' upholstery stud designs could be matched to those from Christ Church, Spitalfields: CCS 3 (coffin 479) and CCS 36b (coffin 1089).

Table 4.2 *Types of metals used for coffin fittings at St Luke's, Islington (n = 750)*

Fitting type	N	Iron	Lead	Silvered tin	Brass	Tin pewter
<i>Departum</i> plates	204	19 (9.36%)	153 (75.37%)	16 (7.88%)	15 (7.39%)	1 (0.49%)

Upholstery studs	123	82 (66.67%)	0	0	41 (33.33%)	0

#### *Departum* plates

*Departum* plates were riveted onto the upholstered coffin in the positions that their individual names suggest (inner, outer, head, foot). All breastplates at St Luke's had inscriptions giving the title, name, age and date of death of the deceased. Occasionally, additional information was included, such as their place of birth or residence, their profession (in the case of a man) or the profession of their father or

husband (in the case of a woman) and relationships to other family members. Inner breastplates usually contained the same information as the outer breastplate, but sometimes contained less detail. The information from the head and footplate inscriptions was usually restricted to the name, title and year of death of the deceased. Such information is a rich source of biographical and palaeodemographic data for the population interred there.

Two hundred and three *departum* plates were recorded from St Luke's (Table 4.2). The majority (n = 204) was made of lead (75.37%). Plates of iron constituted 9.36%; silvered tin, 7.88%; brass, 7.38% and tin pewter 0.49% of the assemblage. Lead breastplates were heavily decorated with stamped motifs and borders. The symbolism underlying these motifs has been discussed above. Many breastplates were too corroded for their styles to be identified. Sufficiently well preserved breastplates were compared to the Christ Church, Spitalfields taxonomy (Reeves and Adams 1993). Matches were found in 100 cases (49.26%). These comparisons are of significance in refining the date ranges during which specific styles were in use in the late Georgian/early Victorian period. In addition to known styles, 46 new breastplate styles (OLR 1- 46) were identified at St Luke's church on 87 individual breastplates. These were sketched on site and comprise Figures 4.1-4.56. The number of breastplates in each new style is listed below in Table 4.3. Date ranges are also given. Of the new styles, OLR 29 was the most popular (eg Fig. 4.40), Date ranges are also given. On comparing these new breastplate styles with those identified at St George's, Bloomsbury, seven matches were found (Table 4.1).

*Table 4.3 Summary of the new breastplate styles at St Luke's church, Islington (n = 87). N = total number identified in the assemblage. The numbers quoted in brackets are the number of examples of known date. Date ranges for the new types are given.*

### *Grips and grip plates*

Once solely functional, the grips with which mourners carried the coffin became stylistically elaborate during this period, as did the grip plates through which the grips attached to the coffin. Depending on the coffin size, most coffins originally had between four and ten grips. Pairs of grips and grip plates were attached along the long axis of the coffin. Frequently another pair was attached to the head and the foot of the

coffin. In most cases the grips and grip plates on a coffin matched one another in style and the type of metal used.

Grip plates from 142 coffins were recovered at St Luke's. Many were very poorly preserved, and often consisted of no more than small fragments corroded onto the reverse of the more robust grips. Of those sufficiently well preserved to identify, grip plates from 59 coffins were found to match the Christ Church, Spitalfields taxonomy. The most ubiquitous was CCS 3, found on 30 coffins (50.85%). The popularity of this style is echoed in the assemblages from Christ Church, Spitalfields, (Reeve and Adams 1993); St George's, Bloomsbury (Boyle *et al* in prep), and St Bartholomew's, Penn (Boyle 2004). Frequently, but certainly not in all cases, grip plate CCS 3 and grip CCS 4 were found together as a set. Of the total numbers of grips and grip plates from the four sites, grip plate CCS 3 accounts for 50.44% of the total number of coffins with recognised grip plates; and grip CCS 4 for 35.6% of the grips. In addition to the styles that could be matched to the Christ Church, Spitalfields taxonomy, six new styles of grip plate (OLR 1- 6) were identified (Figures 4.64-4.67). No matches with the new grip plate types were made with the St George's, Bloomsbury assemblage.

Coffin grips were recovered from 243 coffins at St Luke's church. Being predominantly of iron, many had suffered considerable corrosion, and the style of decoration could not be identified. One hundred and thirty five were matched to the Christ Church, Spitalfields taxonomy. In addition, nine new styles (OLR 1-9) were identified (Figures 4.57-4.63), of which one (OLR 7, Figure 4.63) could be matched to a grip from St George's, Bloomsbury (BBM 2).

Needing to be robust, the metals used for grips were restricted to iron and brass, whereas a greater variation in materials could be used for the grip plates. At St Luke's, iron was overwhelmingly the most favoured metal for grips, constituting 99.18% of the total assemblage. The remaining grips were of brass. Iron was also the most popular metal for grip plates (85.92 %), followed by tin pewter (8.45 %), lead (4.23 %) and silvered tin (1.41 %).

Table 4.4 Summary of new types of coffin fittings, other than breastplates, identified at St Luke's church, Islington ( $n = 57$ ).  $N$  = total number of examples of each style found, with datable examples in brackets. The known date ranges are also given.

### *Lid motifs*

Lid motifs and escutcheons are decorative stamped pieces of metal attached to the upholstery of the outer wooden case. Lid motifs are larger than escutcheons and tend to be located above the head and in the knee area of the coffin lid. Escutcheons are most commonly found in the corners and along the margin of the upholstery stud-work panels of the coffin lid and side panels.

Relatively few lid motifs were recovered from St Luke's Church. This is probably more a factor of poor preservation rather than a genuine absence from the

original assemblage. The vast majority of lid motifs were composed of very thin sheets of stamped iron. Only 23 lid motifs were recovered from the site. It is probable that many more had rusted away altogether. The lid motifs at St Luke's church were made of iron (73.91%); tin pewter (17.39%) and of lead (8.7%). Thirteen motifs were matched to the Christ Church, Spitalfields taxonomy. Using the St Luke's material, it is now possible to date three lid motif types. In addition, four new types were identified (OLR 1- 4), three being flaming urns (Figs 4.69-4.71), and one a *resurgam* motif (Figure 4.72).

#### *Escutcheons*

Escutcheons were recovered from 15 coffins at St Luke's Church. In common with lid motifs these metal fittings are made of very thin stamped metal, and hence, are more prone to corrosion than more robust fittings, such as breastplates and grips. It is thus probable that the original prevalence of escutcheons was very much higher than was recovered during the excavation. There was much greater variation in the materials used for this form of coffin decoration. Escutcheons from eight coffins were composed of iron (53.33%), four of tin pewter (26.67%), two of brass (13.33%) and one of silvered tin (6.67%). Stylistically, escutcheons from 20 coffins were matched to the Christ Church, Spitalfields taxonomy. One new style was identified (OLR 1; Figure 4.73).

#### *The distribution of coffin types at St Luke's Church*

The general condition of the coffins at St Luke's church varied greatly, the coffins within the earth-cut graves of the churchyard being worst preserved, and the interments in the crypt best preserved. At St Luke's Church, remnants of coffins survived in association with 712 of the total of 1048 burials (67.94%)<sup>3</sup>. It is assumed that all burials were originally contained within a coffin, as was the common burial practice, in all but the most extreme cases of poverty, in this period. However, natural decay of wooden coffins, particularly in earth-cut graves, has removed all traces of the original coffins. Table 4.5 below summarises the coffin materials and coffin types found in the churchyards and the crypt of St Luke's Church.

---

<sup>3</sup> A further five skeletons were identified during osteological analysis bringing the total to 1053.

Table 4.5 *Summary of coffin types and materials (n=712)*

Material	Single	Double	Triple	Total
Wood	254	0	0	254
Lead-lined	0	14	439	453
Iron	3	0	0	3
Zinc	1	0	1	2
Total	258	14	440	712

There is a marked patterning to the distribution of coffins of different type and materials as demonstrated in Table 4.6. Wooden coffins were found predominantly in the earth-cut graves of the churchyards (92.19 %). Only one was present within the crypt, whilst a more mixed picture emerged in the brick-lined shaft graves and extramural vaults. Of the 62 burials within these structures, 35.48 % (n = 22) were of wood. Extramural vaults had a lower proportion of wooden to lead coffins (34.21 %) than brick-lined shaft graves (55.88 %). The remaining coffins were lead-shelled coffins, with the exception of three iron coffins and two zinc coffins. Non-lead metallic coffins began to be used in the mid-19th century, being cheaper than wooden coffins, and lighter than a lead equivalent, but like lead they provided a water and airtight container for the corpse. However, they never achieved much popularity with the public, and even less so with incumbents of the Church, taking a long time to decay. Additional charges by the Church for burial within such coffins also contributed to their unpopularity (Litten 1991).

*Table 4.6 Location of coffins of different materials within the churchyards and crypt of St Luke's church, Islington (n = 1048)*

Location	Coffin not extant	Wood	Lead-shelled	Zinc	Iron
Northern churchyard earth-cut graves	274	86	17	0	0
Southern churchyard earth-cut graves	56	150	45	1	3
Total extra-mural earth-cut graves	330	236	63	1	3
Northern churchyard vaults and shaft graves	1	2	17	0	0
Southern churchyard vaults and shaft graves	4	15	23	0	0
Total vaults and shaft graves	5	17	40	0	0

Location unknown	1	0	0	0	0
Totals	336	254	453	2	3

The distribution of the different coffin types within the churchyard and the crypt of St Luke's suggests a strongly hierarchical approach to the most socially desirable place of burial across the site. Overall, earth-cut graves were the most humble and least desirable, followed by brick-lined shaft graves, then extra-mural vaults, and the most desirable of all, interment beneath the living body of the church itself. The southern churchyard would have been a more desirable place of burial than the northern churchyard because the church entrance was on the south side and consequently burials would have been more visible there. Burial fees were greater and this is further reflected in the higher numbers of lead-shelled coffins there when compared to the northern churchyard (see Table 4.6).

### **Grave clothes and grave goods**

Janaway (1998) comments on the great variation in dressing corpses in the 18th and 19th centuries. A loose sheet or winding cloth was often placed under the corpse and used to line the open coffin, and later was folded over to cover the corpse, often being pinned in place. Shroud pins were found in five coffins (428; 468; 947; 985; 1270). A punched lace or ruched ruffle (trimming consisting of frills) often adorned the coffin sides. This has been discussed more fully above.

The corpse itself was often clothed in a crudely made shroud. Nightdress-like shrouds, often with a ruffle round the neck and down the front, began to replace the earlier practice of dressing the dead in everyday personal clothing in this period

(Janaway 1998). One male skeleton (coffin 778) at St Luke's was discovered with a trouser button overlying his pelvis, suggesting that he was wearing trousers at the time of burial. The lack of other such fastenings suggests that most individuals buried at St Luke's were dressed in shrouds. In a number of lead coffins, shroud fragments were found adhering to the bone. Seventeen coffins contained shroud material. In most cases the fabric was not identified. In coffins 354 and 966, woollen shrouds were identified, whilst a shroud of linen was discovered within coffin 1022.

Three female skeletons had a textile frill around the skull (468; 491; 526). In coffin 524 this fabric was very well preserved and was clearly a bonnet. One male (coffin 162) wore a length of green and cream silk pleated and folded around his neck. The excavator interpreted this as a cravat.

In keeping with Christian beliefs of the period, very few coffins contained grave goods or even personal affects. Exceptions were coffin 871, which contained a single gold earring; coffin 959, a copper alloy coin; 1013, a bone handle from a piece of cutlery.

## Conclusion

The coffin fittings from St Luke's church constitute an important new corpus that makes a valuable contribution to the growing body of knowledge about the material culture of funerals in the late Georgian/early Victorian era. Although much is known historically about Victorian burial traditions, examination of the physical remains of the coffins and other funerary accoutrements is a relatively new and exciting field. Comparisons with Christ Church, Spitalfields, St George's Church, Bloomsbury (Boyle *et al* in prep.) and St Bartholomew's Church, Penn, Wolverhampton (Boyle 2004), have refined the dating of many known fitting styles. Many date ranges of coffin fitting styles from Christ Church, Spitalfields, have now been greatly expanded, suggesting that numerous styles remained in vogue for up to 150 years. Others appear to have enjoyed much more transient popularity. However, such research is still in progress, and as the coffin fitting corpus expands with the addition of data from more sites in the future, a more comprehensive picture should emerge.

In addition, to furthering our knowledge of existing fittings, 67 new types have been identified at St Luke's church, and will be added to the 'master catalogue' in progress. It is hoped that this information will be available to excavators of future

post-medieval burial sites, and that this valuable research will be carried forwards in the future.

Table 4.7 Summary of styles of coffin fittings from 18th- and 19th-century churches based on typologies from Christ Church Spitalfields (CCS)

## CHAPTER 5 THE HUMAN SKELETAL ASSEMBLAGE

*by Ceridwen Boston, Angela Boyle and Annsofie Witkin*

### Introduction

A total of 1053 skeletons were excavated at St Luke's church. Of these, 896 were recorded osteologically. Two hundred and forty-one individuals were named, whilst 655 were unnamed. The assemblage of unnamed individuals was recorded osteologically using low resolution methodology, whilst the 241 named individuals underwent full analysis. It would not be meaningful to compare the prevalences of many skeletal pathologies and non-metric traits between the two samples. For this reason, the two groups have been treated as separate assemblages in this chapter.

The presence of a fairly large skeletal assemblage of known age and sex allowed a rare and valuable opportunity to test frequently used osteological ageing and sexing methodologies for accuracy and precision. The value of new ageing methods was also examined against the known chronological age of these skeletons.

One hundred and fifty-seven burials were not osteologically recorded for one of two reasons: either the coffins were sealed or substantially intact, or the remains were fleshed, and therefore deemed unsuitable for osteological analysis.

### Osteological analysis of the unnamed sample

The identity of 655 individuals buried at St Luke's church could not be ascertained from *departum* plate inscriptions. Although a number of unnamed individuals were discovered within the crypt ( $n = 54$ ) and extramural vaults and brick-lined shaft graves ( $n = 27$ ), the majority of the unnamed population was recovered from earth-cut graves within the northern and southern portion of the churchyard ( $n = 574$  or 87.63%). This is in part due to the poorer preservation of coffin furniture within these graves, and in part reflecting simpler burial practices of many churchyard burials at St Luke's church. In the Georgian and Victorian periods, the church vault was the most socially desirable location for burial, followed by extramural vaults and brick-lined shaft graves. An earth-cut grave was the cheapest and least favoured place of

interment, and was the lot of the more humble members of society. Thus, palaeodemographic differences between the unnamed and named skeletal populations at St Luke's church may reflect real socio-economic differences between these contemporary, but socially distinct populations. However, comparisons between the two populations are hampered by the differences in methodology used in the recording of many pathologies.

## Methodology

Unlike the named sample that underwent full osteological analysis, the unnamed skeletons were examined in less detail. Age, sex and stature were analysed fully, bone preservation and completeness were recorded, and a full skeletal and dental inventory was made. The skeletons were not formally examined for skeletal pathology or non-metric traits, but those pathologies or traits noted incidentally in the course of osteological examination were recorded. Dental pathology was also recorded. As a result of this methodology, the true pathology rates for this sample may be under-reported.

Adults were aged using a combination of methods, including ageing from the degeneration of the pubic symphysis (Suchey and Brooks 1990; Todd 1921), iliac auricular surface (Lovejoy *et al* 1985) and sternal rib ends (Iskan and Loth 1984; Iskan *et al* 1985), and from cranial suture closure (Meindl and Lovejoy 1985). The dental attrition method of Miles' (1962) was not employed, as this tends to grossly under-age skeletons of post-medieval populations. Instead, the method developed by Roden (1997) on a post-medieval pauper assemblage from Newcastle Infirmary, Newcastle-upon Tyne, was used. Subadults were aged by dental development (Moorrees *et al* 1963) and by epiphyseal fusion (Bass 1987; Schwarz 2000).

Sexing of adults was determined from the skull and pelvic morphology (Buikstra and Ubelaker 1994), and from metrical data (Workshop 1980). No attempt was made to sex subadults, in accordance with accepted practice.

The stature of the adults was estimated from combined long bone length measurements, using the regression formulae developed by Trotter (1970). Wherever possible, combined femoral and tibial measurements were used. In the absence of either bone, stature was calculated using one long bone, preferably from the lower limb, but where this was unfeasible, the upper limb long bones were utilised.

## Preservation and completeness

Bone preservation of the unnamed assemblage was rated on a four-point scale, ranging from 1 (poor) to 4 (excellent). A wide variation in preservation was noted, with 401 (61.22 %) being rated as well to excellently preserved, 217 (33.12 %) had fair preservation, and 37 (5.65 %) were poorly preserved.

In many skeletons, small bones (such as carpals and phalanges) were under-represented. This is probably due to a combination of poor retrieval of these elements in the sub-optimal lighting of the vaults and from the backfill of earth-cut graves, and the poorer bone preservation of these small, less robust bones. Completeness of the skeleton was scored on a four-point scale, 4 representing 76-95 % completeness; 3 representing 50-75 %; 2 representing 25-49 % completeness, and 1 representing less than 25 % complete. Preservation and completeness of each skeleton is summarised in Table 1 below.

*Table 5.1: Completeness and preservation of the unnamed assemblage (n = 655)*

Completeness	Number of individuals	Preservation	Number of individuals
1 (poor)	114 (17.4%)	1 (poor)	37 (5.65%)
2	172 (25.95%)	2	217 (33.13%)
3	157 (23.97%)	3	338 (51.60%)
4 (excellent)	212 (32.37%)	4 (excellent)	63 (9.62%)
Total	655		655

Table 5.3 shows the category of preservation in relation to location within the churchyard or crypt. The best bone preservation was found in skeletons buried in the earth-cut graves of the southern and northern churchyards. Good to excellent bone preservation was found in 60.47% and 64.35% of these burial groups, respectively; compared with 24.09% and 50% of those buried within the extramural vaults in these locations. It is probable that the structural collapse of many arches and side walls of the extramural vaults contributed towards poorer bone preservation and fragmentation in these groups. Of the crypt burials, 59.26% were rated as being well preserved, whilst 40.74% were poorly or fairly poorly preserved.

*Table 5.2 Preservation and location of the unnamed population within the church precinct (n = 655)*

	1 (Poor)	2	3	4 (excellent)	Total number of individuals
South churchyard	11	74	113	17	215
South churchyard, vault	3	14	1	5	23
North churchyard	16	112	196	35	359
North churchyard, Vault	1	1	1	1	4
Crypt	6	16	27	5	54
Total number of individuals	37	217	338	63	655

Table 5.3 shows the category of completeness in relation to location within the churchyards or crypt. Three hundred and sixty-nine individuals (56.34% of the total burial assemblage) were more than 50% complete, whilst 401 (61.22%) were well or excellently preserved. Skeletons excavated within the northern churchyard and the crypt were most complete, 75% and 66.67% being more than 50% complete, respectively. There was little difference in completeness noted between skeletons from the northern and southern churchyards' earth-cut graves (57.67% and 55.15%, respectively). Least complete were skeletons recovered from within the vaults of the southern churchyard. Of these, only 39.13% were more than 50% complete. The structural damage and depth of these structures and the poorer preservation of this burial group may have hindered the recovery of a greater proportion of the bones of these skeletons.

*Table 5.3 Completeness and location of the unnamed assemblage within the church precinct (n = 655)*

	1 (Poor)	2	3	4 (excellent)	Total number of individuals

Total number of individuals	114	171	158	212	655

## Assemblage composition

### *Sex distribution*

The proportion of adult males and females within the unnamed population is summarised in Table 4 and Figures 1 and 2 below. A total of 41 adults (6.25%) could not be osteologically sexed, as they lacked the diagnostic elements necessary for sex determination. No attempt was made to sex the 102 subadults (15.56% of the total population) in accordance with accepted practice. However, two older adolescents were identified as female on the basis of pelvic morphology.

On the face of it, there appears a slight predominance of males over females (270 or 52.53% versus 244 or 47.47%). However, this male/female ratio is broadly in keeping with deaths with listed in the London Bills of Mortality of 1790-1840 (taken from Molleson and Cox 1993, 208), where males constituted 50.3-52.3%, and females 48.9-49.9% of recorded deaths.

### *Age distribution*

The unnamed individuals ranged in osteological age from foetal to 70+ years. Due to the limitations of current ageing methods, it was not possible to determine the true age of most skeletons beyond the age of 60 years. It is probable that some individuals did survive well into old age (as is suggested from age at death recorded on *departum* plate inscriptions and parish burial records of this time period). Three skeletons could not be aged at all (0.46%), and 56 (8.59%) were identified as adults, but more precise age estimation could not be made. Age estimates were sorted into ten age bands or categories for analysis purposes (see Table 5.4 below).

The assemblage was composed predominantly of adults (84.36%), with only 102 skeletons (15.64%) being aged below 18 years.

Table 5.4: Age and sex composition of the unnamed population (n = 655)

Sex	Foetus	Neonate	Infant 1	Infant 2	Juvenile	Young adult	Prime adult	Mature adult	Ageing adult	Adult	?	Total
		(0-11 months)	(1-5)	(6-11)	(12-17)	(18-25)	(26-40)	(40+)	(50+)			
M						9	67	83	45	9		213
M?						3	20	20	5	9		57

F						17	49	63	45	4		178
F?					2	5	14	20	13	12		66
?	3	25	45	17	10	2	13	1		22	3	141
Total	3	25	45	17	12	36	163	187	108	56	3	655
%	0.40	3.83	6.90	2.61	0.84	5.52	25.0	28.68	16.56	8.59	0.46	

In pre-modern societies, infant mortality rates are considerably higher than modern western societies, and one would expect that this would be reflected in the archaeological record. In 1840, Edwin Chadwick calculated childhood mortality from seven different regions of England from current mortality figures. Although considerable regional variation did exist, he estimated that on average one in five children of the gentry and professional classes would die before reaching adulthood, whereas amongst the children of labourers, servants and artisans the figure was one in two (Rugg 1999, 216-7). Malnutrition, infectious diseases and poor living conditions were the major causative factors for these early deaths.

It is unclear why there is such an under-representation of infants and children at St Luke's church, since the burial ground was fully excavated, and presumably realistically reflects the assemblage composition of the burial population. It is possible that the very young were buried at a different burial site but, given the propensity for burying family members together, this explanation seems unlikely. It is possible that this negative bias may be explained in terms of the poorer preservation of subadult remains, or less successful retrieval during excavation. Over a hundred years of intercutting of graves may also have obliterated smaller infant and child burials. Since the charnel from St Luke's church was not osteologically analysed, the numbers of subadults in this collection is unknown.

Overall, the age distribution of the unnamed sample shows the highest age of mortality in the mature adult age band (aged 40+ years), followed by the prime adult category (26-40 years). Deaths in early adulthood (in females, most commonly from complications of pregnancy and childbirth, and in males, from trauma) were low, involving only 5.52% of the total unnamed population. No marked difference in mortality patterns could be discerned between the sexes.

### *Race*

Cranial and facial dimensions were not systematically measured on the skulls of the unnamed assemblage, and hence, racial identity was not formally assessed. It is

OLP00

assumed that the vast majority of the assemblage was Caucasian. A notable exception was skeleton 1130, a mature adult whose facial features and proportions (eg. the nasal and orbital indices) were more characteristic of an individual of negroid or mixed race.

The presence of a black individual in the St Luke's burial population should not come as a great surprise, given the number of black people documented as living in London in the late Georgian/early Victorian period. Although historical records do record the presence of small numbers of black people in Britain from Roman times, it was with the expansion of the British Empire and the establishment of the slave trade that the numbers of blacks in Britain grew dramatically. Many were employed as domestic servants to wait on wealthy families, whilst others were sailors, professional boxers or undertook a range of menial jobs. Whilst the majority appeared to have lived in penury, a handful did achieve wealth and social position. For example, Cesar Picton, a former servant, became a moderately wealthy coal merchant and land owner in Kingston-upon-Thames, and Olaudah Equiano (1745-1797), a former slave, went on to become a radical reformer and best-selling novelist (Sandhu 2003). The true number of black people living in London in this period is difficult to gauge, but in 1764, the *Gentleman's Magazine* estimated a number as high as 20,000 individuals; like skeleton 1130, the vast majority of these were male (*ibid*).

### ***Stature***

It was possible to estimate the stature of 295 males and 238 females (81.37% of the total adult population). The male stature range was 1.49-1.94 m (mean of 1.71 m or 5 foot 6 inches), whilst the female range was 1.39-1.74 m (mean of 1.58 m or 5 foot 2 inches). This is comparable with the named population from St Luke's church, where the mean statures for men and women were 1.70 and 1.58 m, respectively.

Childhood and adult stature is determined by an interplay of inherited and environmental factors. Whilst we all have a maximum genetic potential to reach a certain adult stature, physical and emotional stressors during childhood and adolescence may prevent us achieving this potential. If such stressors (such as malnutrition, infection or chronic illness) are too severe or prolonged for the growing body to 'catch-up' growth later, the individual will become permanently stunted. Thus, stature has been used as a rough yardstick to indicate the overall health of

*Table 5.5 Comparative data on stature estimation in seven later post-medieval urban populations in England*

	Male (Mean)	Male (Range)	Female (Mean)	Female (Range)
St.Luke's,Islington (unnamed)	1.70 m	1.49 m-1.94 m	1.58 m	1.39 m-1.74 m
St.Luke's,Islington (named)	1.70 m	1.55 m-1.93 m	1.58 m	1.49 m-1.72 m
Newcastle Infirmary	1.71 m	1.60 m-1.83 m	1.60 m	1.50 m-1.76 m
St Bartholomew's, Penn	1.75 m	1.45 m-1.85 m	1.60 m	1.42 m-1.83 m
St Nicholas, Sevenoaks	1.73 m	1.62 m-1.83 m	1.61 m	1.49 m-1.72 m
St George's, Bloomsbury	1.72 m	1.52 m- 1.85 m	1.60 m	1.49 m-1.72 m
Christ Church, Spitalfields	-	1.68 m-1.70 m	-	1.54 m-1.59 m
Cross Bones, Southwark	1.69 m	1.53 m-1.80 m	1.58 m	1.42 m-1.72 m
Kingston-on-Thames, London	1.69 m	1.54 m-1.90 m	1.60 m	1.40 m-1.75 m

individuals and of populations, provided the genetic component of populations do not change (as would happen, for example, with an influx of peoples of different average stature). Because the unnamed individuals of St Luke's church had largely been buried in earth-cut graves, the more simple form of burial at this time, it was probable that they represent the working classes of the Islington area, whilst the named individuals (who predominantly were buried in more elaborate coffins in the church crypt, vaults or brick-lined shaft graves) represent the middle classes. A higher stature was expected of the latter group, given their greater access to better food, medical care, physically less onerous jobs and general living conditions. This was not found to be the case. There is no difference in the average stature of men and women, and only a slight difference in the range of statures.

When comparing the average stature with other contemporary burial sites in England (Table 5 above), it is interesting to note that St Luke's named and unnamed assemblages had average male stature that was lower than the pauper burial ground of the Newcastle Infirmary, Newcastle-upon-Tyne, and only a centimetre greater than the poor buried at the Cross Bones burial ground, Southwark, and the middle classes of Kingston-upon-Thames. Average male stature was noticeably lower than the crypt burials of St Nicholas', Sevenoaks, St George's, Bloomsbury and St Bartholomew's, Penn. These assemblages represented the upper middle classes of the period. Less variation was found in female stature across the six sites, with St Luke's named and

unnamed female stature being the lowest comparable only to that of the Cross Bones burial assemblage in Southwark, and two centimetres less than the other four sites. It is unclear why the St Luke's assemblages have statures lower than expected, given the greater wealth of that part of London, relative to working class Southwark and the working classes of Newcastle Infirmary.

### **Dental pathology**

Dental pathology was recorded in 230 individuals of the unnamed assemblage. Teeth were fully analysed for calculus, periodontal disease, caries, abscesses and antemortem tooth loss (AMTL). Gross dental enamel hypoplasia was also recorded. Caries, abscess and AMTL rates were not calculated per tooth or socket but per individual. Unfortunately, this had precluded meaningful comparisons with the named assemblage from St Luke's, Islington, and from other sites of this period. Dental disease prevalences are displayed in Table 5.6 below.

In the post-medieval period, the consumption of cane sugar gradually increased. In the 16th and 17th centuries, sugar was an expensive and high status luxury available only to the most wealthy. However, the development of sugar plantations in the West Indies in the 18th century generated a more ready and affordable supply of the commodity to markets in Europe. Sugar consumption gradually spread down the social classes, until by the latter half of the 19th century it was available to all but the most indigent. By the early 19th century, sugar was widely available to the middle classes, but was not yet cheap enough to be readily accessible to the lower classes. The availability of sugar had a dramatically deleterious effect on the dental health of the nation. Caries rates doubled from the late medieval to the post-medieval period and antemortem tooth loss increased by 4% over the same period (Roberts and Cox 2003, 396).

### ***Dental calculus***

Plaque is composed of oral micro-organisms that become imbedded within a matrix of protein, saliva and food residues that accumulate on the teeth after eating. Carbohydrates, particularly simple sugars, accelerate this process (Hillson 1996, 254-55). Plaque may become mineralised, forming calculus, the hard immovable deposit on the teeth colloquially known as tartar. There are two types of calculus: supra-

gingival calculus, which is situated above the gum line, and sub-gingival calculus found beneath the gum line on exposed roots. Deposits are most heavy on teeth nearest to the saliva glands (Roberts and Manchester 1995, 55). Regular brushing of the teeth will remove most plaque deposits, thus preventing calculus formation.

The calculus rate was recorded per tooth present, and size and position on the crown was noted, using guidelines set out by Brothwell (1981). However, such a detailed presentation of this data is beyond the scope of this report. Calculus was recorded on the teeth of 16 individuals in the unnamed assemblage. This was graded as flecks only in one individual, as slight in 11 others and moderate in three. The low prevalence and lack of severity of calculus deposition is surprising in an age where dental hygiene was minimal or entirely lacking, but may relate to a low consumption of refined sugar by this population.

### *Periodontal disease*

Periodontal disease is the inflammation of the soft tissues of the mouth, namely the gums, and/or the periodontal ligament and alveolar bone (Levin 2003, 245). Retraction of the gums exposes the vulnerable root of the tooth to attack by acidic plaques, commonly resulting in caries, abscesses and ante-mortem tooth loss. The main predisposing factor for periodontal disease is calculus build-up in the dental pockets. Periodontal disease is strongly associated with increasing age in both modern and archaeological populations. However, aetiology of this disease is multi-factorial, with genetic predisposition, environment, diet and oral hygiene all playing a role.

The disease may express itself as either horizontal or vertical bone loss. In the former, more than one tooth is affected, often involving the whole dental arcade, with all alveolar walls being lost uniformly. This is by far the more common form of periodontal disease. In vertical bone loss, the lesion is localised around one or two teeth. This bony resorption around the tooth is irregular, and generally occurs without horizontal bone loss (Hillson 1996, 263-65).

Periodontal disease was recorded by subdividing the jaws into four quadrants, which was scored independently. The severity of the disease was scored as slight, medium or considerable, using the universally accepted standards set out by Brothwell (1981). In the unnamed sample, periodontal disease was present in 46 individuals. It ranged in severity from slight ( $n = 7$  or 15.22% of the cases of

periodontal disease present), through medium ( $n = 15$  or 32.61%) to considerable ( $n = 22$  or 47.83%).

### *Caries*

Destruction of the tooth enamel results in the formation of caries, which is irreversible and frequently results in toothache, abscess formation and ultimately, ante-mortem tooth loss. In the unnamed assemblage ( $n = 230$ ), 188 carious cavities were recorded, giving a prevalence of 0.81 caries per person. Dental caries develop as a result of poor oral hygiene and a diet high in carbohydrates, particularly processed sugar.

### *Ante-mortem tooth loss (AMTL)*

Although teeth were sometimes drawn electively, in anticipation of the agonies of toothache in later life, or lost as a result of trauma, most teeth were lost as a result of periodontal disease and caries. AMTL is diet-related but also age-related, and hence, it is no surprise that the older members of the unnamed population suffered higher rates of tooth loss. In the unnamed population, 1219 teeth were lost ante-mortem. This is an average of 5.3 teeth per individual.

### *Dental abscesses*

Severe dental disease may result in infection tracking down to root canal or around the root to the apex, resulting in a dental abscess. In untreated cases, the pressure of the inflammation and accumulated pus forces a path through the alveolar bone, leaving behind a smooth-sided lesion in the jaw. In the unnamed population, 92 such abscesses were present, a prevalence of 0.4 per individual.

### *Dental enamel hypoplasia*

Dental enamel hypoplasia (DEH) manifests on the buccal surface of the tooth crowns as pits, horizontal lines or lines of pits. These features are the result of a thinning of the enamel caused by an interruption or slowing of the normal deposition of enamel during crown formation (Goodman and Rose 1990). DEH is induced by a number of metabolic insults, such as nutritional deficiency, weaning and bouts of childhood diseases lasting more than three weeks (Aufderheide and Rodriguez-Martin 1998; 405; Hillson 1996, 165-66). Unlike bone, enamel does not remodel during life, and so

remains as a permanent indicator of such a stress episode in the first six or seven years of life.

In the unnamed sample, the dentition was not systematically analysed for DEH, and hence, fainter lines were not recorded. One individual (skeleton 247) showed marked enamel thinning, indicating very severe, prolonged ill health in childhood. The underlying stressor could not be identified in this skeleton, but malformation of the cusps of the mandibular molars of seven adult skeletons (608, 783, 954, 975, 997, 1024 and 1258) were the mulberry molars typically found in congenital syphilis. The disease and its manifestations are discussed in more detail in the section on skeletal pathology below.

### ***Dental interventions***

Two individuals (skeletons 290 and 975) had metal fillings in their molars. The latter had suffered malformation of enamel (mulberry molars) due to congenital syphilis, which would have left the teeth more vulnerable to decay. Indeed, this prime adult male had seven unfilled caries at the time of death. Four teeth had been filled: three with gold and one with lead. Skeleton 290 had a single filling of the right upper maxillary molar. The material was described as a grey metal, and is most likely to be tin, lead or mercury amalgam.

During the 18th and 19th centuries, the cheapest material used for fillings was either tin or lead. From the beginning of the 19th century, various forms of amalgams became available. These were based on heavy metals, such as mercury, which was mixed with copper or silver filed from coins (British Dental Association Museum display; Hillam 1990). Pellets of the amalgam were placed in the cavity and tamped down with a hot instrument. Gold was the most suitable material but also the most expensive. A typical dentist's fees of 1781 listed gold fillings at 7/6 whilst lead fillings cost 5 shillings each (Wilson 1985, 38). Gold fillings were made of tiny pieces of gold foil that were compressed into the dental cavity.

### Skeletal pathology

Although the unnamed sample was not formally examined for pathology, large number of bones displayed obvious evidence of pathological conditions. Detailed information on the location and character of these bony changes is available in Table 5.6 below.

It is important to reiterate that because the skeletons were not formally examined for pathology, a number of more subtle bone modifications may have been overlooked, and hence, the rates calculated here might be erroneously low. This is especially true for periostitis and well healed and well aligned fractures. Spinal degenerative joint disease (SDJD) was fully recorded and does reflect the true prevalence of these degenerative changes.

### ***Congenital disorders***

A number of congenital anomalies were present in the unnamed sample. Many of them would not have affected the health or daily lives of the individuals concerned. However, some would have had deleterious effects and are discussed below.

#### ***Spondylolysis***

Spondylolysis is the ossification union failure of the *pars interarticularis* of the vertebra, resulting in separation of the vertebra into two parts: a ventral part formed by the body, pedicles and transverse and superior articular processes, and a dorsal part formed by the laminae, spinous process and inferior articular processes. Spondylolysis has long been considered to be a congenital disorder, but more recent work also suggests a traumatic origin. It is frequently associated with another common neural tube defect: *spina bifida occulta* (Aufderheide and Rodriguez-Martin 1998

Health problems may arise from spondylolysis through slippage of the vertebral bodies, due to the lack of the anchoring effect of the inferior articular process. Most commonly, L5 slips on the sacrum, but L3 on L4, and L4 on L5 does occur. The fifth lumbar vertebra of skeleton 682 showed non-union of the *pars interarticularis*. The sacrum of this individual was normal.

#### ***Scoliosis***

Severe congenital scoliosis affected the spine of skeleton 723. Scoliosis is the abnormal curvature of the spinal column to the left or right in the coronal plane. It differs from kyphosis, which is the abnormal curvature in the antero-posterior plane (colloquially known as a hunchback). In skeleton 723, there was marked deviation to the left, with the spinal column between T3 and T9 at an angle of 60° to the midline. The bodies and facets of these vertebrae were fused, and five to six ribs were fused to the internal organs, particularly the lungs, would have been compressed, possibly causing respiratory problems as well as an increased risk of blockages in the intestines. This type of spinal deformity may be caused by trauma (Aufderheide and Rodriguez-Martin 1998, 66-67), but the severity of the deformity in this individual, and the morphological changes to the ribs indicate that the scoliosis was congenital. In skeleton 756, there were developmental abnormalities of the sacral segments S1-3. The anterior half of the sacral bodies has a cleft in the body, causing a right-sided scoliosis of the sacrum. The body of L5 is deformed and wedged thereby correcting the scoliosis of the sacrum superiorly.

### *Other vertebral congenital anomalies*

In a one-year old child (skeleton 881), three consecutive neural arches were fused together. It is unclear if this was congenital or the result of trauma.

### *Os acromiale*

During normal development, the acromial process begins to fuse to the scapula at approximately 10-14 years (Schwartz 2000). In some adults, non-union persists into adulthood, and is known as *os acromiale*. Originally believed to be a developmental anomaly, work on skeletons from the ship the *Mary Rose*, which sank off the coast of England in 1545 AD, suggests an occupational role in the development of this condition (Roberts and Manchester 1995, 113). In the *Mary Rose*, 13.6 % had *os acromiale*, in comparison with modern dissection room frequencies of 8.0 %. The highest frequency was found amongst skeletons located where archery equipment was stored, suggesting that prolonged archery practice from childhood was a factor in the aetiology of this condition.

In the unnamed St Luke's assemblage, *os acromiale* was identified on the right scapula of two skeletons (512 and 808). It is unclear how much genetic variation or repetitive arm movements sustained from childhood into adulthood underlay the development of this condition. In a society where child labour was commonplace, it is not improbable that repetitive arm motions enacted over many years of childhood, adolescence and adulthood (for example, weaving or minding a machine) caused or contributed towards this condition.

### *Congenital shortening of the femur*

Shortening and abnormal medial rotation of the left distal femur was present in a mature female (skeleton 160). The proximal third of the femur was normal, but the distal two thirds of the femoral shaft and the condyles were medially rotated, such that the anterior aspect of the bone faced medially. The left tibia appeared normal, and must have been held in a medially rotated position, since no secondary degenerative changes were present in the knee or ankle joint of the left foot. The maximum length of the left femur was 47 mm shorter than the right. This congenital anomaly would have caused an inward rotation of the foot, and a pronounced limp whilst walking.

In the absence of any pathological evidence, it would appear that this deformity was congenital in origin, and is typical of one of four main forms of congenital femoral shortening, which occur unilaterally in 90% of cases (Aufderheide and Rodriguez-Martin 1998, 71).

## *Trauma*

### *Fractures*

Fifty-five unnamed individuals (8.3%) displayed fractures indicative of trauma. Nineteen fractures were defined as closed, and involved principally the ribs in nine individuals, the upper limbs in eight individuals, and the lower limbs in four. Evidence of healing and good alignment of the bone were present in most of the above bones, but due to callous formation the type of fracture could not be ascertained without radiography.

Fractures may be defined by their nature and their anatomical alignment relative to the long axis of the bone. In the unnamed assemblage, seven oblique fractures, seven transverse fractures, one comminuted fracture and 19 compression fractures of the vertebral bodies were identified. The location of oblique fractures varied from the distal tibial shaft (skeleton 232), to the glenoid fossa (skeleton 244), the left fibula shaft (skeleton 457), and the distal shaft of the left radius (skeleton 1177). All these fractures were largely or completely healed. Most common transverse fracture sites were the ribs (usually occurring as the result of a direct blow to the ribcage), the distal radius and the neck of femur and the distal fibular shaft. Compression fractures of the vertebrae most commonly affected the mid to lower thoracic vertebral bodies.

Malalignment of fractures was relatively rare, suggesting that splinting of broken long bones was successfully undertaken in most cases. There were, however, several exceptions. On the radius of skeleton 232, no overlap occurred, but the apposition of the bone fragments had been less carefully maintained, and the distal portion of the element was angled anteriorly at 20° to the midshaft. This mature female had osteoporosis, which would have rendered her bones more brittle and prone to fracture. A slight fall onto an outstretched hand may well have been sufficient to fracture the bone. Aufderheide and Rodriguez-Martin (1998, 315) report that, together with the femoral neck, the distal radius is by far the most common fracture site in individuals with osteoporosis.

Total failure of the broken bones to knit was observed in the left ulna of skeleton 463. The broken bone had formed a pseudoarthrosis of the olecranon that remained detached at the level of the coronoid process, despite evidence of healing of the proximal and distal ends of the fractured bone. This non-union is due to poor

stabilisation of the broken bone of the elbow joint following the injury, a fracture still problematic to fixate today.

Compression fractures of the bodies of two vertebrae were found in 19 individuals. Crush or compression fractures result when a sudden excessive force is applied to the bone (Ortner and Putsch 1981, 56), and the bone is compressed along the plane of impact (in this instance vertically), either collapsing the body uniformly, or forming a wedge-shaped vertebral body. Crush fractures often occur where there is already an inherent weakness of the bone (most commonly due to underlying osteoporosis, but also present in pathologies such as tuberculosis or metastatic carcinoma). In severe cases, the uneven collapse of the body precipitates a misalignment of the spinal column (scoliosis or kyphosis), which may result in compression of the spinal nerves, causing chronic pain and disturbance of sensation to the peripheries.

Skeleton 838 had suffered a comminuted fracture to the distal shaft of the right tibia and fibula. A comminuted fracture occurs when the bone is shattered by a crush or direct blow, and splinters into a number of fragments at the site of impact. These fractures are notoriously difficult to align correctly, and healing is often slow.

Two fractures were complicated by bone infection. A mid-shaft fracture in skeleton 209 shows new bone growth on the shaft and a large sinus penetrating to the marrow cavity, indicative of secondary osteomyelitis. Skeleton 743 also showed bony changes typical of infection following the fracture of the left distal fibula shaft. Infection following fracture is frequently as a result of the broken bone breaking through the skin (known as a compound fracture) and directly introducing infection into the marrow cavity.

Skeleton 243 had suffered a slipped epiphysis of the left femoral head probably due to a traumatic incidence in childhood or adolescence. The resultant joint surface was elongated and abnormally flattened, and there was a loss of the *fovea capiti*. However, no secondary degenerative changes were noted on the femoral head or left acetabulum, suggesting that the individual walked without difficulty or pain.

#### *Traumatic dislocation of the hip*

Skeleton 838 appears to have experienced an extremely traumatic injury, in which the right femoral head was completely dislocated posteriorly from the acetabulum. The loose femoral head of skeleton 838 had moved superiorly and a new false socket had

developed on the right iliac blade, created by an area of profuse osteophytosis, pitting and eburnation. Similar bony changes are found in cases of severe congenital dislocation of the hip. The femoral head showed eburnation and osteophytosis but otherwise appeared normal. The long bones of the right leg were also normal in size and morphology, suggesting that this injury had occurred in adulthood when full skeletal maturity had been obtained. The presence of the false socket indicates that this ageing male had continued walking after the injury, albeit with a marked limp.

Unlike the shoulder, the hip joint is an extremely stable joint, with the femoral head and acetabulum held in position by a number of large muscles, tendons, ligaments and fascia. Considerable force is necessary to dislocate the hip. In modern examples, the posterior dislocation of the femur is exceedingly rare, and is most commonly the result of severe force applied through the knee when the casualty is in a sitting position (for example, hitting the dashboard of a car in a head-on road traffic accident (Hacking 2004, pers. comm.). In late post-medieval London, such an injury may have been sustained from a severe fall onto an outstretched leg.

### ***Metabolic disorders***

#### *Cribra orbitalia and porotic hyperostosis*

*Cribra orbitalia* is widely thought to occur in response to a deficiency of iron during childhood, most commonly the result of inadequate dietary intake of iron, and/or as a result of severe intestinal parasite infestation (Stuart-Macadam 1991, 101). Iron is a central component of haemoglobin, the molecule necessary for the transportation of oxygen in the red blood cells of the blood. Red blood cells are produced within the red bone marrow of a number of bones of the body, which include the diaphysis of the cranial vault, the sternum and the pelvis. In childhood the diaphyses are particularly important, but become a secondary site of red blood cell production later in life. In iron deficiency anaemia, the body attempts to compensate for low serum iron levels by hypertrophy of these bones. In children, this manifests osteologically as an increased porosity and thickening of the diaphysis of the cranial vault (known as porotic hyperostosis) and of the orbital sockets (*cribra orbitalia*). *Cribra orbitalia* is often used as a generic indicator of physical stress in childhood.

Thirteen adult and five subadult skeletons displayed *cribra orbitalia* (2.60 % of the total population). These lesions were graded in severity, using the standards set out by Stuart-Macadam (1991, 101-113). In most individuals, the lesions were scored

as Type 2 or 3 (slight to moderate severity). The lesions were active in all the subadults. Porotic hyperostosis, manifesting as pitting of the left and right parietal bones, was also present in mature adult skeleton 892 and in prime adult skeleton 957.

### *Scurvy*

Three individuals (skeletons 529, 678 and 1284) presented with lesions of the eye orbits characteristic of scurvy, although in skeleton 1284 a differential diagnosis of scurvy or *cribra orbitalia* was problematic.

Scurvy is a disease caused by a prolonged deficiency of vitamin C, usually due to a dietary inadequacy of fresh vegetables and fruit. Scurvy develops gradually over several months, lethargy being present from 12 weeks, lumps and haemorrhages of the skin and mucous membranes occurring between 19-23 weeks, and swollen, soft purple gums appearing after 30 weeks (French 2003, 297). Scurvy causes lack of wound healing and haemorrhaging, cardiac haemorrhages occasionally resulting in death. Skeletally, scurvy is noted from hypertrophy of the diploë in the eye sockets and cranial vault, and diffuse new bone growth on the periostium in response to haemorrhage adjacent to the bone (Aufderheide and Rodriguez-Martin 1998, 310-312).

Scurvy famously afflicted sailors on long sea voyages, but outbreaks also occurred sporadically in other social groups (such as long-term prisoners), and it was prevalent amongst agricultural labourers during years of poor harvests, the most severe being the potato famine of 1845-46 (French 2003, 296-7). In the 18th and 19th centuries, the supply of fresh vegetables and fruit to the metropolis of London was frequently very erratic, and the cost was often beyond the meagre means of the urban poor. Infantile scurvy also followed the early weaning of infants onto pap or panada, a mixture of flour and water (Roberts and Cox 2003, 307), which was grossly lacking in many nutrients (see also rickets for vitamin D deficiency). This child-rearing practice was often popular amongst the affluent, and hence, scurvy cannot be seen solely as a deficiency disease of the poor.

### *Rickets*

Anterior-posterior bowing of the femoral shafts and/or medio-lateral bowing of the tibiae diagnostic of rickets was observed on seven skeletons (1.07%). Rickets is a deficiency disease caused by a lack of vitamin D, which is central to the absorption of dietary calcium. A deficiency results in soft, thin bones. Weight-bearing during crawling and walking in childhood cause the long bone shafts of the arms and legs to

bow. Although Vitamin D may be obtained in foodstuffs such as oily fish and animal fat, the majority of vitamin D is formed by the exposure of the skin to ultraviolet radiation. The presence of rickets usually indicates an individual who had not received sufficient exposure to sunlight in early childhood.

Rickets was fairly uncommon in pre-industrial and rural agrarian societies (Ortner and Putschar 1981, 274), but became widespread in the industrial cities of the later medieval period. The smog that blanketed the great manufacturing centres (including London) for much of the year served to block out a great deal of sunlight. Long hours of child labour in factories and mines also ensured that many working class children were not exposed to sufficient daylight necessary for the adequate production of vitamin D. In 1773, Fordyce (quoted in Roberts and Cox 2003, 309) estimated that 20,000 poor children in London were afflicted with this disease. The scale of the disease was still vast in the mid-19th century, with a third of all admissions to Great Ormond Street Hospital in London being diagnosed as rachitic.

However, rickets was not necessarily the sole preserve of the poor. The 17th century physician Francis Glisson (the first to describe rickets in precise clinical detail) observed that it was a disease of children of the wealthy classes, where it was common practice not to be suckled one's natural mother, but by a wet nurse (Sloan 1996, 44). This practice usually resulted in early weaning onto gruels high in calories but poor in animal fat, and hence, low in vitamin D (Steinbock 2003, 281-282). This social practice resulted in those from a privileged background developing the disease, and was exacerbated by keeping the young child indoors for long periods.

### *Osteoporosis*

Osteoporosis is a proportional decrease of both the bone mineral and the bone matrix, leading to bone which is light and brittle, and liable to fracture after minimal trauma (Steinbock 2003, 236). There are two types of osteoporosis: type 1 or post-menopausal osteoporosis (affecting women over 50 years of age), and commonly the underlying condition in vertebral crush fractures and fractures of the distal radius; and type 2 or senile osteoporosis, which affects both males and females over the age of 60 years equally, and predisposes individuals to vertebral wedge fractures and fractures of the femoral neck. A drop in oestrogen levels following the menopause accounts for 10-20% loss of total bone mass in modern women (*ibid*). This often serves to aggravate a pre-existing negative calcium balance caused by a poor dietary calcium

intake and/or the net bone calcium lost during the reproductive years through multiple pregnancies and prolonged breastfeeding (*ibid*):

Osteoporosis affected three unnamed individuals (skeletons 252, 267, and 893). The first two were mature and prime adult females, respectively. The age and precise sex of adult skeleton 893 is not known. Given the ages of skeleton 252, it is more probable that she suffered type 1 osteoporosis, whereas skeleton 267 may have suffered either type 1 or 2. Skeleton 252 had suffered spinal complication secondary to osteoporosis with severe compression fractures of T8, L1 and L2. Given the difficulty in macroscopic identification of osteoporosis, it is highly probable that the true prevalence was very much higher in this population.

### *Joint disease*

#### *Ankylosing spondylitis*

Possible ankylosing spondylitis was observed on the vertebral column and pelvis of skeleton 498, with fusion of the sacro-iliac joint, and of four pairs of adjacent thoracic and lumbar vertebrae. However, the female sex and presence of osteoarthritis in other parts of the skeleton makes this diagnosis less certain.

Ankylosing spondilitis (AS) is a systemic, non-infectious, progressive inflammatory disorder of connective tissue calcification (Roberts and Manchester 1995, 118-120; Aufderheide and Rodriguez-Martin 1998, 102). The aetiology of the disease is poorly understood, but there appears to be a strong autoimmune causation. It is a rare disease affecting only about 1 in 2000 individuals, 90% of which are male (*ibid*).

The sacro-iliac joint, spine and major peripheral joints are most frequently involved. The disease process usually begins in early adulthood, classically with erosion, new bone growth and ankylosis or fusion of the sacro-iliac joint and calcification of associated ligaments. Typically in ankylosing spondylitis, the lower thoracic/upper lumbar vertebral bodies and small vertebral joints begin to fuse, and the intervertebral disks and longitudinal ligaments ossify. This process progresses up and down the spinal column (but more typically the lumbar vertebrae are first to fuse), creating the classic 'bamboo spine' of this disorder.

Table 5.7: Summary of the pathology identified on the skeletons of the unnamed population (n = 262).  
Abbreviations: R = right; L = left; C = cervical vertebrae; T = thoracic vertebrae; L = lumbar vertebrae; SDJD = spinal degenerative joint disease, OA = osteoarthritis.

Inhumation	Pathology	Comments
<b>Congenital disorders</b>		
682	Spondylolysis	L5: Pars interarticularis or spondylolysis
1003	Congenital spondylolysis	C2 and 3: bodies are fused at articular surfaces, as are half of the spinous processes. Intervertebral disc space is not preserved
<b>Spondylolysis</b>	<b>2</b>	
512	<i>Os acromiale</i>	R scapula: tip of acromium process has remained unfused
808	<i>Os acromiale</i>	R scapula: tip of acromium process has remained unfused
<b><i>Os acromiale</i></b>	<b>2</b>	
756	Deformity of sacrum and L5	Anterior half of sacral bodies S1-3 have cleft in bodies, causing R sided scoliosis of S1-4; Deformity of body of L5 with L body compressed, thereby correcting sacral scoliosis
723	Scoliosis	Severe scoliosis of T3-T9 at a 60° deviation to the L from the long axis to the L, with bodies and facets fused, and 5-6 ribs fused to vertebrae
<b>Scoliosis</b>	<b>2</b>	
881	Fusion of vertebral neural arches	Three neural arches fused together (? developmental defect, ? trauma) in a year old child
<b>Fusion of vertebral neural arches</b>	<b>1</b>	
160	Congenital shortening of the femur	Congenital deformity of L femur (47 mm shorter than R). Upper third normal. Distal half of femur and condyles medially rotated.
<b>Congenital shortening of the femur</b>	<b>1</b>	
<b>Trauma</b>		
209	Closed fracture	Mishaft fracture of R humerus, alignment poor: angled medially at 45° to long axis of bone; Large sinus indicating osteomyelitis; traumatic arthritis to humeral head (profuse osteophytosis and porosity)
213	Closed fracture	Healed fractures of R radius, 2 x R-ribs, R patella, C6
248	Closed fracture	L radial proximal shaft: large callous, medial displacement of shaft; secondary osteomyelitis
277	Closed fracture	L clavicle mid-shaft: large callous formation, slight inferior displacement of lateral fragment; R 2nd metatarsal: callous present, well aligned
376	Closed fracture	5 ribs healed
473	Closed fracture	Distal shaft of L fibula: callous still just visible, well aligned
479	Closed fracture	Distal R radial shaft: largely healed (callous just visible); slight misalignment of fragments
506	Closed fracture	R clavicle, 2nd metacarpal, 5 ribs (probably right)
569	Closed fracture	Posterior R rib shaft: fracture with overlap of fragments anteriorly, and fusion onto the adjacent inferior rib
575	Closed fracture	Well healed fracture from unsided rib fragment (callous still present)
652	Closed fracture	R clavicle: healed fracture resulting in callous formation and shortening of bone
681	Closed fracture	L 10th rib: healed fracture
743	Closed fracture	L distal fibula: partly healed fracture of shaft, with secondary osteomyelitis
803	Closed fracture	R humerus: healed fracture of medial epicondyle
847	Closed fracture	L mid-thoracic rib: large callous formation, partly healed, well aligned
870	Closed fracture	L rib: anterior part of rib has healed fracture
886	Closed fracture	Un-sided ribs x 2: healed fracture of shafts; R patella: healed fracture of lateral side; R 1st metatarsal: healed fracture with secondary osteoarthritis (eburnation and severe osteophytosis).
1015	Closed fracture	1 x L rib: fracture at angle of rib

1242	Closed fracture	R fibular and tibial shafts: distal ends on medial aspect; healed
<b>Closed fracture Count</b>	<b>19</b>	
190	Compression fracture	Compression of entire body of T8 and anterior wedging of T9
195	Compression fracture	Anterior wedging of T6 and T7, associated with osteochondritis and osteophytosis
252	Compression fracture	Severe compression fracture of T8, L1 and L2, secondary to osteoporosis
265	Compression fracture	Compression fractures of T6-T9, causing kyphosis (? underlying osteoporosis)
274	Compression fracture	Complete severe compression of C6; anterior wedging of C7
280	Compression fracture	T10: anterior wedging of body, associated with severe osteoarthritis
282	Compression fracture	Anterior wedging of body of T10
348	Compression fracture	L5: severe compression of whole body
463	Compression fracture	T11 and T12
506	Compression fracture	T8 and T9
572	Compression fracture	C6: severe compression of body
662	Compression fracture	Severe compression of body of T8 with resultant kyphosis, associated with SDJD
665	Compression fracture	T3-6 are fused at bodies, T5 body wedged resulting in slight scoliosis of spine- ? traumatic in origin
742	Compression fracture	Wedging of body of T9 to R side, causing slight scoliosis, associated SDJD
822	Compression fracture	Anterior wedging of body of T5, with fusion of T5 and T6, associated with SDJD
1051	Compression fracture	L5: wedging of body towards R
1167	Compression fracture	T10 and 11: wedging of bodies resulting in a scoliosis to the left
1280	Compression fracture	T6: severe compression of whole body; T5: slight wedging of anterior body associated with slight SDJD of thoracic vertebrae
1281	Compression fracture	T3-T7 bodies fused, bodies wedged to L causing slight scoliosis
<b>Compression fracture Count</b>	<b>19</b>	
838	Comminuted fracture	R distal tibial shaft and fibula: well aligned and well healed fracture, but caused shortening of limb by 2.5 cm
<b>Comminuted fracture</b>	<b>1</b>	
242	Transverse fracture	Malformation, misalignment and medio-lateral flattening of femoral head-old fracture of femoral head
519	Transverse fracture	L rib
687	Transverse fracture	R tibia: distal shaft immediately proximal to the distal end: well-aligned and well healed fracture, slight callous and thickening of shaft still present
736	Transverse fracture	L humerus: oblique or transverse fracture of mid-shaft, healed; severe medial angulation of distal humeral shaft (c. 45°)
738	Possible transverse fracture	R acetabulum and R proximal femur: severe porosity, moderate to severe osteophytosis, flattening of the femoral head, secondary to neck of femur fracture
815	Transverse fracture	Rib fragment (possibly L): well healed fracture, no significant callous formation
850	Transverse fracture	Distal shaft of 5th R metatarsal: long standing healed fracture
<b>Transverse fracture Count</b>	<b>7</b>	
232	Oblique fracture	Distal shaft of L tibia (well aligned and marked callous formation)-well healed
244	Oblique fracture	Circular defect in scapula fossa from trauma
329	Oblique fracture	Healed fracture of R femoral neck with subluxation of head and neck and profuse callous formation
457	Oblique fracture	L midshaft of R fibula: large callous formation, in good alignment
687	Oblique fracture	Distal end of R fibular shaft: callous is still evident, but healing advanced, slight anterior displacement of distal shaft, immediately superior to the malleolus
870	Oblique fracture	L 3rd metatarsal: oblique mid-shaft fracture well healed, slight overlap of fragments
1177	Oblique fracture	Well-healed but poorly aligned fracture of distal L radius
<b>Oblique fracture Count</b>	<b>7</b>	
463	Pseudoarthrosis	Non-union of L ulna olecranon process
<b>Pseudoarthrosis Count</b>	<b>1</b>	
243	Dislocation of the epiphyseal plate	Healed slipped proximal epiphysis of L femoral head causing abnormal flattening of head, no secondary DJD

<b>Dislocation of the epiphyseal plate</b>	<b>1</b>	
838	Traumatic dislocation of hip	R pelvis: false socket immediately superior to acetabulum (area of profuse osteophytosis, pitting and eburnation) where femoral head articulated with pelvis; caused by posterior dislocation of R hip joint
<b>Traumatic dislocation of the hip</b>	<b>1</b>	
453	<i>Osteochondritis dissecans</i>	L humeral head: ovoid loss of bone on posterior articular surface
567	<i>Osteochondritis dissecans</i>	Medial condyles of R and L femora: small circular areas where dense bone is absent on the joint surface
576	<i>Osteochondritis dissecans</i>	Olecranon process of R ulna: ovoid smooth lesion on joint surface with trabecular bone clearly visible
826	<i>Osteochondritis dissecans</i>	Circular lesion located medially on L humeral head
1112	<i>Osteochondritis dissecans</i>	Lateral condyle of distal L femur
<b>Osteochondritis dissecans</b>	<b>5</b>	
<b>Metabolic disorders</b>		
225	<i>Cribra orbitalia</i>	Type 3 R orbit
232	<i>Cribra orbitalia</i>	Type 2 L orbit, Type 1 R orbit
237	<i>Cribra orbitalia</i>	Type 2, left orbit
257	<i>Cribra orbitalia</i>	Type 3, left and right orbits
293	<i>Cribra orbitalia</i>	Type 2 L and R orbits
348	<i>Cribra orbitalia</i>	Type 3 R and L orbit
587	<i>Cribra orbitalia</i>	Type 1 healed L and R orbits
606	<i>Cribra orbitalia</i>	Type 4-5 R and L orbits, active
608	<i>Cribra orbitalia</i>	L and R orbits, active
685	<i>Cribra orbitalia</i>	L and R orbits: Type 1 (healed)
703	<i>Cribra orbitalia</i>	L and R orbits: Type 1 (healed)
802	<i>Cribra orbitalia</i>	L and R orbits: porous bone
814	<i>Cribra orbitalia</i>	R orbit: Type 1
816	<i>Cribra orbitalia</i>	L and R orbits: Type 2 (active)
892	<i>Cribra orbitalia</i>	Porotic hyperostosis of L and R parietals, <i>cribra orbitalia</i> of L and R orbits
905	<i>Cribra orbitalia and porotic hyperostosis</i>	L and R orbits: pitted; parietals have thickened porous bone typical of porotic hyperostosis
957	<i>Cribra orbitalia</i>	Porotic hyperostosis of cranial vault; bilateral lesions within orbits
1025	<i>Cribra orbitalia</i>	L and R orbits: Type 1-2, healed
1124	<i>Cribra orbitalia</i>	L and R orbits: active lesions
<b>Cribra orbitalia Count</b>	<b>19</b>	
252	Osteoporosis	Of spine
267	Osteoporosis	Underlying SDJD
479	Osteoporosis	Bones very light, associated with SDJD and fractured R radius
893	Osteoporosis	Bones are light in weight, associated osteoarthritis
<b>Osteoporosis Count</b>	<b>4</b>	
529	Scurvy	New bone formation on the roofs of the L and R orbits
678	Possible scurvy	L and R orbits: pitted lamella bone
1284	Possible scurvy or <i>Cribra orbitalia</i>	L and R orbits: Type 5 <i>Cribra</i> - trabecular bone and new bone outgrowths (active); difficult differential diagnosis
<b>Scurvy</b>	<b>3</b>	
119	Rickets	R and L femurs and tibiae
221	Rickets	Anterior bowing of R and L femoral shafts. Slight A-P bowing of both tibiae. Periosteal new bone growth (woven) present anterior aspect of R and L tibiae.
236	Rickets	Slight medio-lateral bowing of tibial and fibular shafts, flaring tibial condyles
432	Rickets	Severe bowing of femora, fibulae and tibia.
444	Rickets	Anterior bowing of R and L femoral shafts
489	Rickets	Lateral bowing of tibiae, healed
508	Possible rickets	R and L femora show anterior bowing mid shaft, R more marked and shorter.

645	Rickets	L and R femora, tibiae and fibulae show bowing of shafts typical of rickets, massive thickening of proximal medial aspects of femoral shafts
668	Possible rickets	Slight bowing of femora
673	Rickets	Anterior bowing of femora and lateral bowing of tibiae
686	Rickets	Lateral bowing of tibiae
694	Rickets	Marked anterior bowing of femora; L and R tibiae and fibulae: medial bowing and flaring of tibial condyles
703	Possible rickets	Anterior bowing of L humerus (rickets during years of crawling)
733	Rickets	Lateral bowing of the L and R tibiae
739	Possible rickets	L and R tibiae: medio-lateral bowing of shafts
749	Rickets	R and L rickets: anterior bowing of shafts (healed)
751	Rickets	R and L femora: anterior bowing of shafts; L and R tibiae: antero-lateral bowing of shafts
761	Rickets	Severe anterior bowing of femoral shafts
957	Rickets	Bilateral bowing of tibiae, and shortening
975	Rickets	Slight lateral bowing of tibiae
952	Infantile rickets	L and R distal metaphyses flared, shafts thickened
1020	Infantile rickets	Distal radiae and ulnae; proximal humeri, distal femora and proximal and distal metaphyses flared, and appear 'plump'
1034	Rickets	L and R tibial shafts: bowing
1043	Rickets	L and R femora and tibiae: bowing and thickening of lower mesial femora and upper mesial tibiae
1137	Rickets	R and L femora: shafts have exaggerated curvature and thickening of shafts
1236	Rickets	L and R fibulae very bowed; flaring of metaphyses of all major long bones
1262	Rickets	L and R femora: anterior bowing of shafts; tibiae: medial bowing of shafts
1279	Rickets	L and R femoral shafts: anterior bowing; L and R tibiae: lateral bowing
1287	Rickets	All major long bones: flaring of metaphyses, ribs and long bones very porous; L and R femora: slight anterior bowing; L and R tibiae and fibulae: severe bowing of shafts
1312	Rickets	L and R tibiae: lateral bowing of shafts
<b>Rickets Count</b>		<b>30</b>
<b>Joint disease</b>		
498	Possible ankylosing spondylitis	Profuse osteophytic growth and fusion of sacro-iliac joint; T5-8, T9-11, T12-L3 and L4 and 5 fused-? AS or ? severe OA
<b>Ankylosing Spondylitis Count</b>		<b>1</b>
490	Possible DISH	Fusion of sacro-iliac joint, fusion of L5 and S1, fusion of R proximal fibula to R tibia (no thoracic vertebrae present)
521	DISH	T7-10 fused along the right side of the vertebral column with intervertebral joint spaces preserved
638	DISH	T5-11 fused along right side of the vertebral bodies, ossifications have a candle wax appearance; enthesophyte formation on calcanea, patellae and tibial eminences
817	DISH	T2-12: fusion of bodies along the right side; L1-5: moderate osteophytosis of anterior bodies; enthesophytes on proximal and distal ends of L and R tibiae, fibulae, patellae, and greater trochanter of femora; symphysis pubis fused, sacro-iliac joints fused
850	DISH	T5-7: fused along R side of bodies; T3-L5: large osteophytosis; fused sacro-iliac joint enthesophytes on patellae, posterior calcanea, posterior olecranon of proximal ulna
951	Possible DISH	T7-9: fused with osteophytes of a candle wax appearance; fusion of sacro-iliac joint; too damaged to be certain of diagnosis
996	DISH	T4-11 fused along the R side with dripping candle wax appearance, enthesophytes on patellae, R calcaneus, tibial eminence
1054	DISH	T4-11: bodies fused down R side, osteophyte has dripping candle wax appearance; enthesophytes present on patellae, tibial eminences and Achilles tendon insertion point on calcaneus
<b>DISH</b>		<b>8</b>
190	Degenerative joint disease	Slight osteophytosis of distal L femoral and proximal L tibial joint surfaces; moderate osteophytosis and porosity on the R distal femur and proximal tibia
191	Degenerative joint disease	Osteophytes on joint surfaces of L distal femur, L patella and L proximal femur
217	Degenerative joint disease	Severe left and right distal femoral DJD

224	Degenerative joint disease	Slight osteophytosis of L proximal femur, severe osteophytosis on distal R femur, R tibia proximal, L femur and R acetabulum
234	Degenerative joint disease	Left proximal humerus: moderate osteophytosis and flattening of the head
236	Degenerative joint disease	Slight DJD of R glenoid fossa, and porosity of L acromial facet
265	Degenerative joint disease	Slight in R acetabulum, R and L distal femora and proximal tibiae
268	Degenerative joint disease	Slight to moderate osteophytosis of L proximal ulna
291	Degenerative joint disease	R sacro-iliac joint: slight osteophytosis
321	Degenerative joint disease	L 1st rib fused to manubrium; porosity of manubrium and medial end of L clavicle
347	Degenerative joint disease	Slight osteophytosis of R and L femora and tibiae
365	Degenerative joint disease	Medial clavicles, R humerus and ribs show marked porosity; T11 and 12: osteophytosis and porosity
367	Degenerative joint disease	L and R acetabulae: porosity
374	Degenerative joint disease	Distal tibiae and fibulae, tarsals and metatarsals, femoral heads and distal R femur: marked enthesopathies and lipping
426	Degenerative joint disease	L and R patellae: enthesopathies
498	Degenerative joint disease	L and R proximal femora: osteophytosis and flattening of joint surface. L and R acetabulae: osteophytosis and porosity
636	Degenerative joint disease	L and R proximal tibiae, distal femora and patellae: osteophytosis moderate; Costal rib facets, sterno-clavicular joint and acromio-clavicular joint: osteophytosis
653	Degenerative joint disease	L 1st metatarsal: degenerative changes of distal articular surface
694	Degenerative joint disease	L and R distal femur and proximal tibia: slight to moderate osteophytosis and porosity
740	Degenerative joint disease	Proximal 1st R phalange of foot: slight osteophytosis
741	Degenerative joint disease	L and R patellae, distal femora and proximal tibiae: slight osteophytosis
747	Degenerative joint disease	L and R distal femora: moderate osteophytosis around margin of distal joint surfaces
750	Degenerative joint disease	R glenoid fossa: moderate osteophytosis; R sacro-iliac joint fused
804	Degenerative joint disease	Proximal R humerus: slight porosity and osteophytosis
808	Degenerative joint disease	L and R mandibular fossae: pitting; L and R femora: slight lipping of patellar surfaces
885	Degenerative joint disease	L 1st metatarsal: porosity and lipping
1252	Degenerative joint disease	L and R distal 1st phalanges of feet: osteophytosis
1313	Degenerative joint disease	R clavicle, medial surface: moderate to severe porosity and slight osteophytosis
<b>Degenerative joint disease Count</b>	<b>27</b>	
216	Osteoarthritis	L knee: severe osteophytosis, eburnation, flattening of joint surface and shaft. R tibia: enthesopathy at insertion for ligament; anterior bowing of R and L femur
217	Osteoarthritis	R femoral condyles: slight osteophytosis and porosity, severe eburnation with marked grooving of lateral condyle
227	Osteoarthritis	2 x mid to lower thoracic vertebral bodies: moderate osteophytosis, slight porosity and Schmorl's nodes
232	Osteoarthritis	L knee: slight porosity and osteophytosis of femoral condyles and tibial condyles; R knee: moderate osteophytosis and slight porosity of femoral and tibial condyles
252	Osteoarthritis	Severe osteophytosis, flattening and marked porosity of L acetabulum and L femoral head; R proximal humerus and glenoid fossa: severe porosity, eburnation and osteophytosis
275	Osteoarthritis	R patella: eburnation, severe porosity, moderate osteophytes; Moderate porosity and slight osteophytes on distal R femur; severe porosity on R fibula.
277	Osteoarthritis	L proximal femur, L and R proximal humerus and glenoid fossa, R acetabulum: severe porosity, eburnation, osteophytosis and flattening of joint surfaces
278	Osteoarthritis	Severe eburnation, osteophytosis and porosity of L and R humeral head and glenoid

		fossa, and L proximal femur
280	Osteoarthritis	Severe osteophytosis and porosity of C2- C7, C2 and 3 fused and C5 and 6 bodies fused; similar lesions on T5-L5 with T5-T7 bodies fused anteriorly; R and L distal ulnae and radii: severe porosity, subchondral cysts and osteophytes; L proximal radius: porosity and eburnation; DJD of L and R carpals and metacarpals; distal and R distal humeri: severe porosity and slight osteophytosis; L and R medial clavicles: moderate osteophytosis and porosity; L and R distal femora: severe porosity, moderate osteophytosis
282	Osteoarthritis	Severe osteophytosis and porosity of C3-7 with C5 and 6 fused, fused T5-7 and osteophytosis and porosity in T5-L4
289	Osteoarthritis	Severe porosity and osteophytosis of C1-C7 and SDJD of L1-5, fusion of L5 and S1 with associated porosity and osteophytosis, severe eburnation and grooving of L5 inferior articular surfaces; R distal femur, patella and proximal tibia: severe eburnation, osteophytosis and porosity
348	Osteoarthritis	R acetabulum: severe osteophytosis, moderate porosity, severe eburnation of entire surface; R femoral head: severe porosity, moderate osteophytosis; L5: : severe eburnation and porosity, moderate osteophytosis; compressed body of L5
367	Osteoarthritis	Distal R humerus: eburnation
376	Osteoarthritis	L 1st metacarpal and proximal phalanx at articulation: eburnation and pitting, C3
409	Osteoarthritis	R patella and distal R femur: porosity and eburnation
437	Osteoarthritis	R femoral condyle: severe osteophytosis and eburnation; R tibial condyle, L tibial condyle, L femoral condyle: moderate to severe osteophytosis
438	Osteoarthritis	Severe osteophytosis and porosity in C3-L4 with bodies C5 and C6, T6 and 7, and T8-10 fused
440	Osteoarthritis	L femoral head and L acetabulum : severe osteophytosis, porosity, eburnation and flattening of joint surface; R distal femur: slight osteophytosis
441	Osteoarthritis	L and R proximal femora and L and R acetabulae: severe osteophytosis, porosity and eburnation
453	Osteoarthritis	C4-L5: osteophytosis and porosity of bodies with T4-T10 fused
454	Osteoarthritis	Severe porosity, subchondral cysts, osteophytosis and eburnation of the distal joint surface of L radius. R 2 and 3 metacarpals fused to carpals, osteophytosis, porosity and subchondral cysts of carpals. R and L 1st metacarpals: severe porosity, osteophytosis and subchondral cysts of distal inter-carpal surface
461	Osteoarthritis	1st metatarsal and proximal phalanx: osteophytosis and eburnation of proximal joint surface
498	Osteoarthritis	C5-T12: severe osteophytosis and porosity of bodies, L2-5: osteophytosis and porosity of bodies less marked
503	Osteoarthritis	Distal L and R 1st metatarsals: moderate osteophytosis, slight porosity and eburnation
523	Osteoarthritis	Carpometacarpal joint of R trapezium and R 1st metacarpal: osteophytosis, porosity, eburnation. Similar but less severe lesions on the L side
511	Osteoarthritis	Eburnation of L trapezoid
517	Osteoarthritis	Severe porosity and moderate osteophytosis of medial R clavicular joint
529	Osteoarthritis	L and R femoral condyles: lipping; patellae: eburnation, pitting and lipping
566	Osteoarthritis	R femoral head and acetabulum: severe eburnation and porosity, slight osteophytosis and flattening of head; R distal femur: eburnation, grooving and porosity; R proximal tibia: slight osteophytosis; L femoral head and acetabulum: moderate osteophytosis, porosity, and flattening of joint surfaces
569	Osteoarthritis	R 1st metatarsal: eburnation on posterior aspect of head
584	Osteoarthritis	L and R patellae: lipping, articular surfaces pitted and sclerotic; L and R femoral condyles: patellae surfaces are pitted and eburnated ; margins of joint are lipped
586	Osteoarthritis	L 1st metatarsal and sesamoid bone: distal articular surface on inferior side shows pitting and eburnation
590	Osteoarthritis	L acetabulum: eburnation and osteophytosis; lipping of L and R patellae, distal femur; distal L and R ulnae, L and R radial facets
630	Osteoarthritis	C2-7: proliferation of new bone on body surfaces, pitting, slight lipping; thoracic vertebrae: lipping
636	Osteoarthritis	C5-T7 and L1-5 bodies: osteophytosis and porosity with T2 and 3, and T6 and 7 fused; severe osteophytosis and porosity and eburnation of apophyseal facets of L1-5
654	Osteoarthritis	L femoral head and L acetabulum: severe pitting, lipping and eburnation of joint surfaces
659	Osteoarthritis	L distal femur and L proximal tibia: moderate osteophytosis; L distal femur and proximal tibiae: moderate osteophytosis, porosity and slight eburnation; L and R 1st metatarsals distal joint surfaces: severe porosity and osteophytosis; C5-C7 bodies and L4-L5 inferior and superior articular surfaces: severe osteophytosis and porosity; L4 and 5: severe eburnation also
662	Osteoarthritis	C6-7, T6-12 bodies severe osteophytosis and porosity with T9 and 10 fused; compression fracture of T8 with resultant kyphosis
664	Osteoarthritis	R and L tarsal bones: moderate to severe porosity, eburnation and osteophytosis; L trapezium saddle joint and proximal 1st metacarpal: moderate osteophytosis and severe

		eburnation; L acromial facet and L distal clavicular joint: severe osteophytosis, porosity and eburnation; T7-8: severe osteophytosis of bodies; T1-L5 bodies: severe osteophytosis and porosity
693	Osteoarthritis	1st R metatarsal and proximal 1st phalange: eburnation and lipping of metacarpophalangeal joint surfaces
733	Osteoarthritis	R humeral capitulum: pitting and eburnation; distal articular surface of R ulna: eburnation
739	Osteoarthritis	L and R humeral heads: proliferation on new bone around and on joint surfaces, eburnation and pitting; R 1st metacarpal: R distal joint surface and lunate articular surface
774	Osteoarthritis	C1-T5: osteophytosis; T6-L5: osteophytosis and porosity of bodies
850	Osteoarthritis	L and R 1st metatarsals: distal morphology of joint completely altered by profuse osteophytosis, pitting and eburnation; L clavicle: eburnation and pitting of acromial articular surface; C1 and 2: eburnation and osteophytosis of dens articulation
867	Osteoarthritis	R 1st metatarsal: eburnation of inferior aspect of head
876	Osteoarthritis	C1 and C2: bodies pitted and eburnated; C1-7: severe osteophytosis and pitting of bodies, T9 and 10, L4 and 5: moderate osteophytosis
892	Osteoarthritis	R 1st metatarsal, sclerotic bone; C5 and 6: osteophytosis and porosity; T11-L5: slight osteophytosis, T7-L1: Schmorl's nodes
893	Osteoarthritis	C2-7: osteophytosis, slight pitting and new bone growth on bodies; possible osteoporosis
941	Osteoarthritis	L femoral head: irregularly shaped due to marked osteophytosis around margin of joint surface (particularly inferior aspect); posterior aspect of joint surface: porosity and eburnation; L acetabulum: corresponding eburnation, porosity and osteophytosis of joint surface
945	Osteoarthritis	L 1st metacarpal: distal joint surface lipped, small area of eburnation
951	Osteoarthritis	L and R 1st metatarsals: severe pitting, lipping and eburnation of distal articular surface
984	Osteoarthritis	L4 and L5: lipping, pitting and eburnation of articular surfaces
993	Osteoarthritis	Capitulum of L humerus and proximal head of L radius: severe pitting, osteophytosis and eburnation; L hallux: interphalangeal joint pitted and eburnated; C4-7: moderate osteophytosis and pitting of bodies, C1-7: R superior and inferior facets pitted, lipped and eburnated
1007	Osteoarthritis	T1-12: osteophytosis, eburnation and porosity
1017	Osteoarthritis	R patella and patellar surface of R femoral condyle: lipping and eburnation; R femoral head: lipping of joint surface and new bone formation on surface, and eburnation
1041	Osteoarthritis	Osteophytosis, porosity and eburnation of distal joint surfaces of R and L 1st metatarsals
1171	Osteoarthritis	L acetabulum and femoral head: porosity, eburnation and osteophytosis
1041	Osteoarthritis	L and R 1st metatarsals: lipping and eburnation on distal surfaces
1108	Osteoarthritis	5 x thoracic vertebral bodies: eburnation, pitting and lipping
1112	Osteoarthritis	R femoral head and acetabulum: severe eburnation covering joint surfaces
1130	Osteoarthritis	L 1st metatarsal: distal joint surface lipped and eburnation
1167	Osteoarthritis	L and R femora: pitted, eburnation and lipping of joint surfaces, osteophytosis on surface also; C6 and 7: osteoarthritis; T10 and 11: wedging of bodies
1234	Osteoarthritis	R femoral head: lipping, eburnation of posterior joint surface; T4-7 and T10-11: fusion of bodies; T1-3: eburnation
1245	Osteoarthritis	L and R distal femora and R patellae: marked eburnation and grooving of joint surfaces
1262	Osteoarthritis	L femoral condyle: lipping of joint surface; florid osteoarthritis of R knee
1248	Osteoarthritis	Capitulum of L humerus and L radial head: osteophytosis, slight porosity and eburnation
1268	Osteoarthritis	R femoral condyle: patellar surface heavily grooved and eburnated, porous and sclerotic, lipping
1269	Osteoarthritis	C2-5 superior and inferior articular facets: osteophytosis and pitting marked; C3-5: eburnation also
1276	Osteoarthritis	R scaphoid and trapezium, pisiform, proximal end of 1st metacarpal, 2 proximal and one middle finger phalange: eburnation and lipping; L5: lipping and eburnation
1281	Osteoarthritis	L clavicle, medial surface: severe osteophytosis and porosity; L and R distal femora: severe porosity, osteophytosis and eburnation; L proximal tibia: moderate osteophytosis; C3-C7 bodies: porosity and osteophytosis; T3-T7 bodies fused, bodies wedged to L causing slight scoliosis
<b>Osteoarthritis Count</b>	<b>71</b>	
209	Schmorl's nodes	T6-L4- large, deep Schmorl's nodes, associated with moderate to severe osteophytosis
268	Schmorl's nodes	T8-L3

298	Schmorl's nodes	T8-10
312	Schmorl's nodes	T7, T10-L2
327	Schmorl's nodes	Small, on thoracic vertebrae
447	Schmorl's nodes	T11 to L3 small
458	Schmorl's nodes	T6-T11
463	Schmorl's nodes	T11 T12
501	Schmorl's nodes	Slight on T7-T11
508	Schmorl's nodes	Lower T and L
580	Schmorl's nodes	T6-11
631	Schmorl's nodes	T7-L3
633	Schmorl's nodes	T7 and 8
673	Schmorl's nodes	T8-12 and L1-5
732	Schmorl's nodes	T8-10
746	Schmorl's nodes	T12
753	Schmorl's nodes	T10 (deep lesion)
811	Schmorl's nodes	T6-8 and T11-12, and L2, slight
836	Schmorl's nodes	Superior aspect of T7-T9
865	Schmorl's nodes	L5
866	Schmorl's nodes	T10-12
870	Schmorl's nodes	T6-8, L1-4
875	Schmorl's nodes	T10-11
892	Schmorl's nodes	L1-T7
957	Schmorl's nodes	T8-L4
975	Schmorl's nodes	L2-4
1044	Schmorl's nodes	T7-12
1059	Schmorl's nodes	T5, 7-10, T12 and L2
1117	Schmorl's nodes	T6-12
1120	Schmorl's nodes	T6-12, large
1230	Schmorl's nodes	T11-L1
1240	Schmorl's nodes	T7-9, L3 and 4
1310	Schmorl's nodes	T10-T12
1316	Schmorl's nodes	T5-L1, many large
<b>Schmorl's node Count</b>		<b>34</b>
190	SDJD	T5-L5: slight to severe SDJ, T9 and T10 compressed bodies, fused
191	SDJD	Moderate osteophytosis of L distal femur, L patella and L proximal femur
195	SDJD	Osteophytosis, porosity and Schmorl's nodes on T6 to L5, compression fracture T6 and 7, osteochondritis to anterior body of T6- T8
213	SDJD	Osteophytosis and Schmorl's nodes on C2-C7, osteophytosis of T8-L2
214	SDJD	Osteophytosis and porosity
216	SDJD	Slight osteophytosis and porosity of cervical vertebrae
218	SDJD	Slight osteophytosis and porosity on T2-11 and L5
226	SDJD	Slight osteophytosis of thoracic vertebrae
227	SDJD	Two thoracic vertebrae: moderate osteophytosis, slight porosity and one has slight and severe Schmorl's nodes
234	SDJD	Slight osteophytosis on C7-T5, and L3-L5; Schmorl's nodes present on T12, L1 and L5
244	SDJD	Osteophytosis on thoracic and lumbar vertebrae
245	SDJD	Slight osteophytosis and porosity to bodies of T4-L5, Schmorl's nodes on T4-L5
252	SDJD	Severe compression fractures, and porosity and marked osteophytosis of T5-L2, with
260	SDJD	T5-7, T9-10 and T11-12 bodies fused, Slight lower thoracic
264	SDJD	Severe, lumbar
267	SDJD	Kyphosis T6 to T9, Schmorl's nodes L1-5
268	SDJD	Slight osteophytosis and porosity

269	SDJD	Slight T8 to L3
274	SDJD	Severe osteophytosis and porosity of C1 to T1, T4 to L5. compression fractures C6 and C7
275	SDJD	Slight cervical
278	SDJD	Osteophytosis and porosity to bodies of C2-T1 and L1
279	SDJD	T4, T8-L1: severe osteophytosis and fusion of T8 and T9, slight anterior compression of body of T11
290	SDJD	Cervical fusion
291	SDJD	Slight osteophytosis and porosity in C6-10
297	SDJD	Moderate to severe porosity and osteophytosis on bodies of L3 and L5
314	SDJD	Schmorl's node on a thoracic vertebrae
316	SDJD	Slight osteophytosis and porosity of bodies of T5-7, L3, slight anterior compression of body of T7
319	SDJD	Slight on L4 and L5
320	SDJD	C5-7 bodies fused together
321	SDJD	Slight osteophytosis and porosity on thoracic vertebrae T4-7 and T12
322	SDJD	Osteophytosis, Schmorl's nodes and porosity on C3-7 and T6-L2
348	SDJD	Compressed L5, severe porosity and moderate osteophytosis
359	SDJD	Slight osteophytosis
365	SDJD	T11 and 12: porosity and osteophytosis, T4 to 6 fused
367	SDJD	Moderate osteophytosis and porosity
374	SDJD	Fusion of T5-6 and of T9-12, osteophytosis and porosity
376	SDJD	C4 and 5, L3-5: osteophytosis and porosity
378	SDJD	Slight osteophytosis of L3 and 4
414	SDJD	Porosity of C5-7
419	SDJD	T5: slight osteophytosis
426	SDJD	T5-6 fused
429	SDJD	Osteophytosis, Schmorl's nodes and porosity of L3 to 5
434	SDJD	Osteophytosis and porosity on thoracic and lumbar vertebrae
435	SDJD	Osteophytosis and porosity of thoracic and lumbar vertebrae
437	SDJD	Slight osteophytosis to T3-T8 and L5, osteochondritis of T6 and T7
440	SDJD	Slight osteophytosis and porosity of T12, L4 and 5
457	SDJD	Slight to moderate osteophytosis and porosity
479	SDJD	T5-T12: slight to severe osteophytosis, with T5-T8 bodies fused together
498	SDJD	Osteophytosis of vertebrae
499	SDJD	Severe in cervical and lower thoracic vertebrae
501	SDJD	Slight osteophytosis and porosity of T3 to T11
502	SDJD	Osteophytosis and porosity of C3-T1 bodies; T5-T9, and L4-5. Porosity severe in L5
506	SDJD	Severe osteophytosis and porosity
508	SDJD	Slight osteophytosis of lower T and L
512	SDJD	Moderate osteophytosis of lumbar, slight on T10-12, Schmorl's nodes T12-L5
517	SDJD	Cervical osteophytosis and porosity
519	SDJD	Slight
525	SDJD	T8-10
529	SDJD	T6-10: slight osteophyte formation
566	SDJD	T5-L2: slight porosity and osteophytosis
571	SDJD	C4-7: profuse osteophytosis of bodies with fusion of C4 and 5, and C6 and C7
572	SDJD	Severe osteophytosis of C4-C7, Schmorl's nodes on T9-L3 and L5
574	SDJD	Severe osteophytosis of T5-T11 with fusion of bodies of T5-7; porosity on T10-12
590	SDJD	T4-12: moderate osteophytosis of bodies, with T5-7 fused anteriorly
591	SDJD	Slight osteophytosis of C2-7, T5-9 and L3-4
593	SDJD	Slight osteophytosis of C3, T2-L5
615	SDJD	Cervical osteophytosis and porosity slight
624	SDJD	T10-12: moderate osteophytosis, T7-12: Schmorl's nodes; L4 and 5: Schmorl's nodes
635	SDJD	Slight osteophytosis of bodies of C4-7

642	SDJD	T3-T12: slight osteophytosis of vertebral bodies
647	SDJD	T9-11: slight osteophytosis of bodies
648	SDJD	T3-7, T10 and L5: slight osteophytosis of bodies
651	SDJD	T11, T12 and L5: slight osteophytosis of bodies
654	SDJD	T11-12 and L1-5: moderate osteophytosis; T5-12 and L1-5: Schmorl's nodes
660	SDJD	C3-4, T11-L5: moderate osteophytosis of bodies; T4-T9: severe (bodies fused)
666	SDJD	L2-3: slight osteophytosis of bodies; T9-10 body fused anteriorly; L5 fused to sacrum by facets
668	SDJD	T5-7: anterior aspect of bodies fused on R; T10-11: bodies fused anteriorly; L1: Schmorl's nodes
669	SDJD	T6-12: slight osteophytosis on bodies; T11-12: bodies fused; L1-5: moderate osteophytosis of bodies
681	SDJD	C5-7, T6-L1: osteophytosis and porosity on bodies, with T8-9 fused; T6, T9-11: Schmorl's nodes
687	SDJD	C5 and 6, T5-L5: slight to moderate osteophytosis of bodies
690	Possible SDJD	T7-9: bodies fused together, unclear aetiology but probably degenerative
693	SDJD	C2 and 3: bodies completely fused together
694	SDJD	T5-T12: osteophytosis and porosity of bodies; T12-L5: osteophytosis of articular facets
730	SDJD	T7-10, L3 and 4: Schmorl's nodes; T12 and L5: slight osteophytosis
733	SDJD	L4 and 5 bodies: medial osteophytosis and porosity
735	SDJD	C5 and 6: fusion of articular processes, C7: body pitted; T7-11 bodies: moderate osteophytosis
740	SDJD	T5-10 and L5 bodies: slight osteophytosis
741	SDJD	L4 and 5 bodies: slight osteophytosis, L sacro-iliac joint fused
742	SDJD	T9-10: slight osteophytosis, T11 and 12: eburation of articular processes, compression fracture of T9- wedged to R causing slight scoliosis
750	SDJD	C2-3, T2-7 bodies: osteophytosis; T7-L3; Schmorl's nodes
759	SDJD	L1-4: Schmorl's nodes and slight osteophytosis
795	SDJD	T6 and T7: totally fused
798	SDJD	T7 and 8: fused bodies; T6: slight osteophytosis on body
803	SDJD	T6-12: slight osteophytosis of bodies and Schmorl's nodes
805	SDJD	C6 and 7: severe osteophytosis; T7, 8, 10 and 11: Schmorl's nodes
808	SDJD	C6-T1 bodies: islands of new bone formation on surfaces, pitted; T12-L4: Schmorl's nodes
810	SDJD	C5 and 6: slight to moderate osteophytosis; thoracic and lumbar fragments show severe osteophytosis
822	SDJD	T5-8: and L1-5 bodies: slight to moderate osteophytosis, with anterior compression of T5 and fusion of T5 and 6
838	SDJD	T2 and 3, and T8 and 9: anterior bodies fused
853	SDJD	C1, C2, C5-T12, and L5: osteophytosis and porosity of bodies
867	SDJD	T8 and 9: bodies fused anteriorly; L4: slight osteophytosis of body
873	SDJD	T5-8, T11-L1: slight osteophytosis, L9 and 10 bodies fused; sacro-iliac joints fused
892	SDJD	Osteophytosis of T12-11
1032	SDJD	Osteophytosis of L2-5
1038	SDJD	Slight enthesophytes on L5-T12
1051	SDJD	Wedge-shaped L5 body, osteophytosis of L2-T11
1174	SDJD	T3 to L5 slight enthesophytes
893	SDJD	Osteophytosis on C2-7, possible osteoarthritis of the neck
877	SDJD	C2 and 3 fused at left articular facet; L5: slight osteophytosis of superior facets
879	SDJD	C6 and C7: slight osteophytosis and porosity on the bodies and R inferior articular surface
882	SDJD	C4-5, T3-4, T7-L2: slight osteophytosis and porosity
883	SDJD	T4-8 bodies: fused at articular surfaces; fusion has caused kyphosis
885	SDJD	T8-10 bodies fused; L3-L5: slight tipping of bodies
889	SDJD	Slight osteophytosis and Schmorl's nodes of T8-12 and L5 bodies
915	SDJD	T11, L2 and 3: slight osteophytosis on bodies
932	SDJD	T3-4: fused at articular surface
933	SDJD	T9-10: slight osteophytosis of bodies
941	SDJD	L1-5: considerable osteophytosis on anterior bodies; L1 and 2 fused

956	SDJD	Thoracic bodies: moderate osteophytosis
959	SDJD	T3 and 4: bodies fused anteriorly; T9-10, L3 and 5: slight osteophytosis of bodies
983	SDJD	T7 and 8: fused at articular processes
1004	SDJD	Ankylosis of T10-11, fusion osteophytosis
1014	SDJD	Slight osteophytosis of lower thoracic and lumbar vertebrae
1015	SDJD	T4 and 5: slight osteophytosis; T9-L3: osteophytosis severe on bodies
1021	SDJD	T7-10 bodies: moderate osteophytosis; L1-5 bodies: slight osteophytosis
1030	SDJD	C5-7 bodies: moderate osteophytosis; T8-9: moderate osteophytosis; T10 and L5: slight osteophytosis
1031	SDJD	T6-10: bodies fused together; L3-5: bodies: slight osteophytosis; L5 and sacrum fused
1032	SDJD	L2-L5: slight osteophytosis
1038	SDJD	T12-L5 bodies: slight osteophytosis
1040	SDJD	T2-T12 bodies: osteophytosis, Schmorl's nodes: T7-T9
1045	SDJD	L2-5 bodies: slight osteophytosis
1046	SDJD	C6 and 7: slight osteophytosis; T5-12: profuse osteophytosis with T6 and 7 and T8 and 9 fused; Schmorl's nodes on T10-12
1051	SDJD	T11-L2: slight osteophytosis; T12: Schmorl's node
1115	SDJD	C5-7: slight osteophytosis and porosity of bodies
1183	SDJD	T10-T12 bodies: fused anteriorly, mainly on the right side.
1187	SDJD	Very slight DJD affecting the costal facets of vertebrae
1119	SDJD	C3-5: porosity and some new bone formation on bodies
1231	SDJD	C3-7: moderate osteophytosis; T1-2: slight osteophytosis
1232	SDJD	C4, T4-6 bodies: slight osteophytosis
1233	SDJD	C6 and 7 bodies: slight porosity and osteophytosis
1243	SDJD	T7-9: slight osteophytosis; T10 and 11: severe osteophytosis of bodies and fusion
1247	SDJD	T3-T6 bodies: osteophytosis
1248	SDJD	C3-T9 and L3-L5 bodies: osteophytosis, C3-C7 bodies: porosity; T10: Schmorl's node
1249	SDJD	T1-L5 bodies: osteophytosis, slight on T1-T6, considerable on T7-12 with T10 and 11 fused on the R side
1252	SDJD	L1 body: moderate osteophytosis
1283	SDJD	T9 and 10 bodies: moderate osteophytosis
1297	SDJD	T8-T11: slight osteophytosis of bodies
1313	SDJD	C5 body: Slight osteophytosis
<b>Spinal joint disease Count</b>		<b>152</b>
<b>Neoplasms</b>		
586	Neoplasm	Parietals: crossing sagittal suture is a discrete raised bump on ectocranial surface; Endocranial surface shows marked thinning of table; within this area are fine, raised subcircular lytic lesions, smooth margins
591	Neoplasm	Large neoplasm on occipital bone involving both endo- and ectocranial surfaces
876	Possible ovarian cysts or tumours	Pelvic region: four irregularly shaped ossified masses were present in this region, of sea sponge appearance
<b>Malignant neoplasms Count</b>		<b>3</b>
892	Button osteoma	1x button osteoma on R parietal
1247	Button osteoma	R frontal bone immediately anterior to coronal suture: button osteoma of 1.94 cm diameter
<b>Button osteoma Count</b>		<b>2</b>
<b>Infection</b>		
209	Osteitis	Periostitis and osteitis of distal shaft of lateral R tibia (thickening of shaft, lamellar bone present)
234	Osteitis	Severe osteitis and thickening of L tibial mid-shaft, woven and lamellar bone (periostitis present)
269	Osteitis	L tibia: thickening of proximal shaft, pitted and lamellar bone; medial proximal shaft of R tibia: thickening of shaft, pitted and lamellar bone
313	Osteitis	R tibia
319	Osteitis	Lesions on femoral shafts and 1st metatarsals
878	Osteitis	Profuse osteitis and periostitis of R and L tibiae with flattening of shafts, periostitis of L and R fibulae (partly healed)
1175	Osteitis	Femora and tibiae active lesions
1279	Osteitis	L tibial shaft: mid-shaft and distal part on posterior and medial aspects thickened; L fibula: thickening of shaft; R tibia: medial and posterior thickening of mid-shaft; L ulna shaft: thickening of proximal shaft, above thickening due to new bone formation (striated). This may not be infection but may relate to rickets in this individual.
<b>Osteitis Count</b>		<b>9</b>
209	Osteomyelitis	Secondary to R humeral fracture of midshaft; associated with traumatic arthritis

248	Osteomyelitis	Left radius secondary to fracture of proximal shaft
329	Osteomyelitis	L tibia: large cloaca in mid-shaft surrounded by pitted and striated bone
409	Osteomyelitis	R femur
411	Osteomyelitis	L ulna and radius, R tibia, L and R femur (healed)
569	Osteomyelitis	R radial distal 2/3 of shaft: marked thickening of shaft due to new bone formation, sinus on midshaft (unhealed)- ? secondary to fracture; R ulna shaft has considerable thickening due to osteitis; R distal humerus: thickening of posterior right side of shaft (uptracking infection)
695	Osteomyelitis	L humerus: proximal to mid-shaft thickening due to new bone growth, and sinus present - ? associated with oblique fracture
743	Osteomyelitis	Fracture of distal L fibular shaft with profuse growth of lamellar bone and cloaca present
866	Osteomyelitis	L and R tibiae: new bone formation, lesions healed
892	Osteomyelitis	New bone formation on L and R fibulae and femora
931	Osteomyelitis	R 5th metacarpal: thickening and deformity with sinus present
<b>Osteomyelitis Count</b>		<b>11</b>
191	Periostitis	Distal shaft, medial aspect R and L tibia (striated bone)
209	Periostitis	R and L tibia
217	Periostitis	L and R distal anterior tibial shafts, and distal anterior L femur
234	Periostitis	L tibial mid-shaft: woven and lamellar bone; marked thickening of shaft
245	Periostitis	L tibial mid and distal shaft: thickened, pitted and striated bone on lateral aspect
269	Periostitis	L and R tibia
275	Periostitis	Mid to distal shaft R tibia
278	Periostitis	L and R tibiae: thick, pitted and lamellar bone on medial aspects of mid to distal shafts
280	Periostitis	L and R tibiae: 2/3 of shafts have thick lamellar bone overlying periostium
313	Periostitis	Distal 1/3 of R tibial shaft: swollen bone with pitted and lamellar bone
314	Periostitis	Distal 1/3 of L and R tibial shafts: fine pitted and striated bone on anterior and medial aspects
319	Periostitis	Proximal half of L and R femoral shafts: lamellar bone on anterior aspects of shafts
330	Periostitis	L tibia: small area of pitted and striated bone on medial aspect of distal 1/3 of shaft
374	Periostitis	healed distal tibiae and fibulae
455	Periostitis	Proximal shafts of R and L tibiae: patches of thickened pitted and striated new bone
482	Periostitis	L and R tibial shafts: new bone formation, healed.
519	Periostitis	R and L tibiae
527	Periostitis	L and R tibial and R fibula shafts: mixture of woven pitted and striated bone
588	Periostitis	R tibia: distal shaft on medial aspect, pitted and striated bone
589	Periostitis	R and L tibiae: shaft on medial and lateral aspects, striated bone
595	Periostitis	R and L tibiae: proximal shaft on lateral aspects, striated bone and raised plaque formations (healed)
652	Periostitis	L femur, (distal medial shaft), fibulae and calcanae: partly healed of periostitis
663	Periostitis	L and R tibiae, femora, fibulae and calcanae: new bone formation on periostium
667	Periostitis	Distal L tibia and fibula: new bone growth on periostium
667	Periostitis	R humerus, R radius and R femur, radial shaft very thickened
700	Periostitis	R tibia and R fibula, proximal end on posterior aspect of shafts: plaques or dense new bone (healed) and bony spicules; L tibial shaft, proximal half on lateral aspect: thickening of shaft, healed plaques of new bone
744	Periostitis	L and R tibiae: new bone formation on medial aspect of distal shafts (more severe on R tibia (healed))
811	Periostitis	L tibial mid-shaft: thickened medial aspect of shaft due to pitted and striated lamellar bone overlying periostium
866	Periostitis	L and R tibiae: long standing healed lesions on the medial and lateral aspects of the shafts
892	Periostitis	L and R fibulae: distal half of shaft had spicules and plaques, thickening of shafts; L and R tibiae: thickening of medial and lateral aspect of mid-shaft due to plaque formation
958	Periostitis	L and R fibulae, femora and tibiae
1299	Periostitis	L femur: thick woven bone covering all aspects of shaft. Absent on R femur
<b>Periostitis Count</b>		<b>33</b>
1168	Middle ear infection	L auditory meatus: enlarges meatus with irregular sharp edge; ear canal: enlarged,

		bony plaques and spicules lining walls
1309	Middle ear infection	Lytic lesions on superior surface of L and R petrous bones (7 and 13 mm resp.)
<b>Ear infection Count</b>	<b>2</b>	
875	Mastoiditis	R mastoid process: smooth-walled oval lesion on antero-distally on mastoid
<b>Mastoiditis Count</b>	<b>1</b>	
683	Septic arthritis/ tuberculous arthritis	L acetabulum: severe lytic lesions penetrating joint surface; posterior iliac blade: large lytic lesion perforating bone, circular erosive lesions on anterior aspect also; L femur: femoral head and neck missing but lesser trochanter shows osteophytosis and lytic lesions; L leg and foot bones are atrophied and shorter than the R.
<b>Septic arthritis Count</b>	<b>1</b>	
608	Congenital syphilis	Mulberry molars, flaring of metaphyses of L and R femora
783	Congenital syphilis	Gross malformation and enamel hypoplasia of molars; slight femoral periostitis
954	Congenital syphilis	Thickened long bone shafts and flared metaphyses; malformation of molar cusps
975	Congenital syphilis	Mulberry molars
997	Congenital syphilis	Deciduous mandibular molars: mulberry molars
1024	Congenital syphilis	Hutchinson's malformation of mandibular canines, non-formation of dental enamel on 1st mandibular molars
1258	Congenital syphilis	1st mandibular and maxillary molars: classic mulberry molars; mandibular incisors: Hutchinson's incisors
<b>Congenital syphilis Count</b>	<b>7</b>	
196	Chronic sinusitis	Severe maxillary sinusitis: multiple plaques in L and R sinuses
225	Chronic sinusitis	Huge maxillary dental abscess causing infection- profuse new bone growth within L maxillary sinus
230	Chronic sinusitis	Plaques of new bone overlying base of L and R maxillary sinuses
428	Chronic sinusitis	New bone growth lining the sinus cavities bilaterally
506	Chronic sinusitis	Maxillary
1026	Chronic sinusitis	R maxillary sinus: plaques of lamellar bone overlying normal bone of sinus walls
<b>Chronic sinusitis Count</b>	<b>6</b>	
573	Chronic pulmonary infection/ disease	Healed new bone formation on 4 L and 1 R rib
947	Chronic pulmonary infection/ disease	5 R and 1 L mid-thoracic ribs: active new bone formation on visceral surfaces
1007	Chronic pulmonary infection/ disease	R ribs 5-11: active woven bone on visceral surfaces
<b>Chronic pulmonary infection/ disease</b>	<b>3</b>	
579	Possible tuberculosis	7 R ribs have new bone formation on the visceral surface; L1: 2 smooth-walled lytic lesions in anterior aspect of the body
757	Tuberculosis	3 L and 1 R ribs: new bone formation on visceral surface (L active, R healed); T12: anterior body penetrated by circular lytic lesions; T6-9: more severe but similar lesions with cortex destroyed revealing trabecular bone which has been perforated by smooth-sided lesions
944	Tuberculosis	Destruction and fusion of vertebral bodies, kyphosis on R side. Sacro-iliac fusion. R femur erosive lesion lateral condyle, lipping and osteophytosis
947	Tuberculosis	New bone formation on the visceral surface of 5x R ribs and 1x L rib.
1007	Tuberculosis	R ribs 6-11: active lesions with new bone formation on visceral surfaces
<b>Tuberculosis Count</b>	<b>5</b>	
<b>Other disorders</b>		
1007	Deformed ribs	L and R ribs 5-11: severe angulation of the shafts, with anterior straightening of shafts, possibly due to constriction from wearing corsets
<b>Deformed ribs Count</b>	<b>1</b>	
229	<i>Hyperostosis frontalis</i>	Thickening and uneven deposition of lamellar bone on endocranial surface of frontal bone
287	Endocranial bone growth	Lamellar bone present on endocranial surface of frontal and parietal bones (infant)
645	Endocranial bone growth	Endocranial surface of occiput: lamellar and woven bone overlaying surface -? birth-related trauma; individual had been buried in lime
<b><i>Hyperostosis frontalis</i> Count</b>	<b>1</b>	
319	Cyst	L and R first metatarsals: smooth edged lesions adjacent to or within the distal joint surface
<b>Cyst</b>	<b>1</b>	

993	Cholelithiasis	One gall stone recovered from abdominal region
<b>Cholelithiasis Count</b>	<b>1</b>	
114	Abdominal aortic aneurysm	Erosion of the anterior L side of bodies of L2 and L3
<b>Abdominal aortic aneurysm</b>	<b>1</b>	
594	Paget's disease	Massive disorganisation and thickening of occipital and frontal bones, thickening of femora, humeri, sacrum and vertebrae
1171	Paget's disease	Considerable thickening of mandible
<b>Paget's disease Count</b>	<b>2</b>	

Depending upon the extent of the ankylosis, sufferers of this disorder experience lower back pain, limited chest expansion, immobility, weight loss and fever (Roberts and Manchester 1995, 119).

#### *Osteochondritis dissecans*

*Osteochondritis dissecans* is a fairly common osteological disorder found on the joint surfaces of the major long bones. Physically active young males (such as athletes) are most often affected in the first two decades of life. This disease is due to a significant localised obliteration of the blood supply, causing necrosis of small areas of joint tissue (Roberts and Manchester 1995, 87). Repeated, low-grade, chronic trauma or micro-trauma is thought to play a role in this injury to the blood vessels. The necrotic bone plaque breaks off from the joint surface and may remain loose in the joint, causing chronic pain and often precipitating osteoarthritic changes. Alternatively, the fragment may reattach in its original position or be resorbed, and no further symptoms will be experienced.

Five skeletons in the unnamed assemblage showed evidence of this disorder (453, 567, 576, 826 and 1112). All but one skeleton (576) were male. Two lesions were located on the femoral condyles, two on the humeral head and one on the olecranon of the ulna. None showed evidence of traumatic osteoarthritis.

#### *Diffuse idiopathic skeletal hyperostosis (DISH)*

As its name suggests, DISH is a systemic disorder where additional bone is deposited around a number of joints of the body. This is largely due to the ossification of surrounding ligaments. Typically, DISH begins with ankylosis of the mid-thoracic spine, due to the ossification of the anterior longitudinal ligament and paraspinal tissues. This produces a dripping candle wax appearance along the right side of the bodies of the vertebral column (Roberts and Manchester 1997, 120). This ankylosis extends superiorly and inferiorly along the vertebral column, leading to the gradual and complete fusion of the spine. The most common extraspinal sites to be affected

are the sternal rib ends (where the costal cartilage ossifies) and enthesophytes at ligament and tendon attachment sites at many locations on the skeleton. The underlying cause of DISH is not clearly understood, but appears to be associated with obesity and diabetes mellitus. The age of onset of the disease is usually from 50 years onwards. The disorder manifests clinically as pain, aching and stiffness in the affected joints (*ibid*).

Six definite and two probable cases of DISH were present in the unnamed assemblage from St Luke's church (1.221 %). These individuals displayed the classic ankylosis of the thoracic spine, and many have enthesophytes at tendon and ligament insertion sites, and ankylosis of the sacro-iliac joint in two individuals. Because of the florid nature of this disease, it is probable that the prevalence of DISH in the unnamed assemblage approximates the true rate of this disorder in this population.

*Table 5.8 The prevalence of DISH in five English post-medieval assemblages (figures cited in Roberts and Cox 2003, 311); WC = working class, MC = middle class*

Site name	Total No	Affected	CPR%	Class
St Luke's, Islington (unnamed)	655	8	1.22	Largely WC
St Luke's, Islington (named)	219	5	2.28	Mostly MC
St Bride's lower churchyard	533	10	1.88	WC
Newcastle Infirmary	189	2	1.06	WC
Christ Church, Spitalfields	968	56	5.79	Mostly MC
Kingston-upon-Thames	360	3	0.83	MC
Total	2924	84	2.87	

Table 5.8 shows the prevalence of DISH in six post-medieval burial assemblages. It is interesting to note that the rate of DISH amongst the unnamed population from St Luke's is significantly lower than that in the named assemblage. DISH in the former population more closely approximates the prevalence found in the Newcastle Infirmary and St Bride's Lower Churchyard assemblages (both predominantly working class populations), and is considerably lower than Christ Church, Spitalfields, where DISH was found in numbers far exceeding other sites of the period. These different rates may well reflect the differences between the diet and lifestyle of the urban working and middle classes of the period.

Historical accounts suggest that the diet of the middle classes during the 18th and 19th centuries was high in animal proteins and fats. Meat and alcohol were

consumed in large quantities (Roberts and Cox 2003, 313). A wide variety of fruits and vegetables was also available, albeit seasonally. Sugar was consumed in large quantities by the 19th century. The descriptions of the food served at dinner parties, and written descriptions of the daily menus suggest that over-indulgence was commonplace (Cox 1996, 50-57). The diet of the working classes was very different from the upper and middle class diets. Malnutrition was a regular occurrence, particularly amongst children and women, the majority of the common diet consisting of potatoes and bread, with little protein, fresh fruit or vegetables. Poor harvests and the subsequent rise in the price of grain occurred sporadically throughout this period, leaving the urban poor vulnerable to extreme privation, if not starvation in bad years. Thus, it is not surprising that the prevalence of DISH (a disease linked to corpulence and over-indulgence) was more common amongst the privileged classes than amongst the poor of Georgian and Victorian England.

#### *Degenerative joint disease*

Degenerative joint disease (DJD) is by far the most common joint disease found in skeletal populations, and the unnamed assemblage of St Luke's church was no exception. DJD occurs where there is damage to a joint through over-use (repetitive activity-related trauma) or through general wear and tear of the joint through life. These bone changes are often progressive and hence, correlate closely to the age-at-death of the individual, and on a palaeodemographic level, prevalence relates to the age-distribution of the population under study.

Degenerative changes manifest skeletally as the deposition and/or resorption of bone of the joint surface. Deposition of new bone (or osteophytosis) on or around the joint surface occurs as a compensatory attempt by the body to spread the load by increasing the joint surface area. Where osteophytosis becomes severe, the new bone may cause the joints to fuse together or ankylose. This is most commonly found in the vertebral bodies. When the cartilage overlying the bone at joints is destroyed, the bone may become very dense or sclerotic. Friction between the two bones may cause polishing or eburnation. Bone resorption often occurs concurrently with deposition. Macroscopically, this manifests as porosity of the joint surface. Infiltration of these pores by synovial fluid may cause subchondral cysts to develop, readily visible by radiography, but less obvious to the naked eye (Roberts and Manchester 1995, 112-114).

DJD is an umbrella term describing a number of degenerative joint diseases (including osteoarthritis, rheumatoid arthritis, and psoriatic arthritis) that do not manifest specifically enough to allow for a differential diagnosis. The vertebrae are the most common location for DJD, and this pathology has been listed separately as spinal degenerative joint disease or SDJD in Table 7 above. In addition to the osteophytosis, porosity and eburnation described above, Schmorl's nodes are another skeletal indicator of degenerative changes of the spine. Schmorl's nodes are depressed areas on the anterior and superior aspects of the vertebral bodies where the intervertebral disc contents have herniated and have exerted pressure on the vertebral body. In modern humans, Schmorl's nodes are very common in individuals aged 45 years and more, and are generally held to have few clinical effects (Aufderheide and Rodriguez-Martin 1998, 96), although recent work does suggest that back pain frequently does accompany modern sufferers.

Thirty-one skeletons in the unnamed assemblage were afflicted with non-spinal degenerative joint disease (4.74 %). SDJD was found in 153 adults (23.36 %), with an additional 34 skeletons showing Schmorl's nodes on the vertebral bodies in the absence of other degenerative changes (5.19 %).

#### *Osteoarthritis*

Osteoarthritis is the most common degenerative joint disease in both humans and animals, affecting 90% of modern people over aged 40 years (Denko 2003, 234-236). In its mildest form, osteoarthritis is not symptomatic, but approximately 30% of those showing clinical evidence of the disease do experience joint stiffness and chronic pain (Denko 2003, 235). These symptoms may become severely debilitating, greatly affecting the sufferer's quality of life, activities and earning potential.

In accordance with the recommendations of Rogers and Waldron (1995), osteoarthritis was diagnosed on joints of the unnamed assemblage where eburnation was present, and/or where at least two other features of osteoarthritis was present (namely porosity, osteophytosis or Schmorl's nodes). Osteoarthritis affected 67 skeletons of the unnamed population of St Luke's church (10.22 % of the total population). This prevalence is probably due to the older nature of the St Luke's unnamed population but occupational stress may also have played a role. The joints most affected were the spine, hips, knees and toe joints of the feet (particularly the big toe). This correlates with the general distribution of osteoarthritis seen in many past

and present populations, where the major weight-bearing joints experience the greatest physical stress (Rogers and Waldron 1995, 6).

### *Neoplasms*

#### *Malignant tumours*

The cranial vaults of skeletons 586 and 591 show marked bony changes indicative of malignant neoplasm. Skeleton 591 had a large area of bone growth on the occiput, involving both the endocranial and ectocranial tables. The bony growth on the parietal bones of skeleton 586 suggested a malignant carcinoma of unspecified type but one that elicited both lytic and osteoblastic responses. The large oval growth (measuring 5.5 x 3.28 cm) was centrally located and crossed the sagittal suture at the crown of the head. The margins were clearly defined and possibly sclerotic. On the endocranial surface, there was considerable thinning of the bone, almost perforating the outer table. Five discrete sub-circular lytic lesions were present within this area.

#### *Ovarian cysts or tumours*

Four ossified masses were found within the pelvic region of an older female skeleton (876). These irregularly shaped masses resembled sea sponges. Although their exact nature cannot be determined without more sophisticated analysis, it is probable that they are the calcified remnants of ovarian cysts or tumours.

#### *Benign tumours*

Two skeletons (892 and 1247) had a button or ivory osteoma on the cranial vault. Skeleton 892 had a single lesion on the right parietal bone, whilst skeleton 1247 had one on the right frontal bone (diameter 1.94 mm). Both individuals were ageing adults, a male and a possible female, respectively. Button osteomas are small circular lumps on the ectocranial surface of the cranial vault, most commonly on the frontal bones. They are benign tumours of no clinical significance (Roberts and Manchester 1995, 188). They are more commonly found in males, and frequency rises after the fourth decade of life (Aufderheide and Rodríguez-Martin 1998, 375), as was the case with these two individuals.

### *Infection*

#### *Non-specific infection*

Non-specific infection was noted on the long bones of 52 individuals of the unnamed assemblage. These have been categorised as periostitis, osteitis and osteomyelitis in

Table 5.8 depending of the depth of penetration of the infection into the bone tissue. Other sites of non-specific infection, such as the mastoid process, middle ear, maxillary sinuses and ribs, are listed separately. It is quite probable, given the low resolution analysis used for this assemblage, that the true prevalence was much higher.

#### Periostitis, osteitis and osteomyelitis

In the vast majority of archaeological skeletons, the specific bacteria responsible for bone infection cannot be identified, and it is referred to as 'non-specific' infection. Bone tissue response to infection involves both resorption and proliferation. Inflammation of the periosteum, or periostitis, manifests osteologically as new bone formation on the surface of the bone. Penetration of infection deeper into the compact bone stimulates further osteoclastic activity, leading to noticeable thickening and sometimes, distortion of the bone. This is known as osteitis. Where the infection penetrates into the marrow cavity, resorption causes pitting and thinning of the cortical bone and an enlarged marrow cavity. The pressure of accumulated may cause this debris to burst through the thinned cortical bone, creating a smooth-sided sinus or cloaca (Roberts and Manchester 1995, 126). The pus is then discharged into the overlying soft tissue, spreading the infection further afield.

In the unnamed assemblage, the long bones of 33 individuals had periostitis. By far the most common location of these lesions was the tibial shafts, found in 28 individuals. This is perhaps not surprising, when one considers the lack of soft tissue overlying this bone, particularly on the anterior aspect, and the greater exposure of the lower leg to traumatic insults. In addition, severe peripheral vascular disease (common in the elderly, those with arteriosclerosis and diabetes mellitus) often result in arterial and venous ulcers of the feet and lower legs that are notoriously slow to heal, and vulnerable to secondary infection. Spread of infection did occur in many cases, most commonly to the fibula, but also to the femur and calcaneus. In most cases, the lesions were either fully or largely healed, showing lamellar and smooth bony plaques.

Eight individuals showed evidence for osteitis. Here too most lesions were located on the tibiae and were largely or fully healed. Thickening of the bone shafts due to reactive bone proliferation was present.

Osteomyelitis is the most severe form of bone infection, penetrating to the marrow cavity. The capacity of the body's immune system to mount a defence against

this infection is severely hampered by the relatively small blood supply to bone tissue. Even today, in an era of sophisticated medical care and antibiotic treatment, osteomyelitis remains one of the most difficult infections to treat. In the unnamed assemblage, 11 skeletons showed evidence of this disorder. In four skeletons (209, 248, 569 and 695), osteomyelitis appeared to be associated with a fracture (presumably a compound fracture where the broken bone penetrated the skin and provided a portal of entry for bacteria). In skeleton 569, a possible fracture and secondary osteomyelitis of the right distal radial shaft caused uptracking infection that spread to include much of the upper limb, with marked thickening of the shaft of the adjacent ulna and humerus (Plate 5.1). In skeleton 411, healed lesions were present on the left ulna and radius, the right tibia and the right and left femora. The widespread distribution of the infection suggests that the causative organism was spread systemically, although a more specific identification of the disease was not possible.

#### Otitis media

The ears of two skeletons (1168 and 1309) showed evidence for chronic *otitis media* or middle ear infection. In the former, the left auditory meatus was enlarged and had a sharp irregular edge of new bone. Deeper within the ear canal, bony plaques and spicules overlay the walls. In skeleton 1309, bony resorption associated with middle ear infection was so severe that lytic lesions had penetrated the superior aspects of the left and right petrous bones. The diameters of these lesions measured approximately 7 and 13 mm respectively. It is probable that this ear infection may have spread, causing potentially fatal meningitis or encephalitis in this adult.

The bony changes noted in the above two skeletons indicate prolonged infection, which would have caused considerable pain. Perforation of the ear drum occurs in many untreated modern cases of *otitis media*, and hence, it is likely that these individuals also suffered hearing impairment.

#### Mastoiditis

A small smooth-walled lesion was present on the antero-distal aspect of the mastoid process of the left temporal bone of skeleton 875. Mastoiditis is the infection from the porous tissue of the mastoid process, and frequently is caused by infected material of a middle ear infection bursting into the surrounding tissue (Roberts and Manchester 1995, 132). Mastoiditis is potentially fatal if the infection spreads internally to the brain and meninges. However, the evidence of a small sinus on the exterior of the

mastoid process of skeleton 875 suggests that instead, the lesion had drained externally, probably resulting in a complete recovery.

#### Chronic sinusitis

Chronic sinusitis was of the unnamed assemblage. The maxillary sinuses of these individuals were exposed due to the post-mortem fracturing of the maxillae. It is highly probable that the true prevalence of the disorder was very much higher but could not be observed in skulls where the facial bones remained intact. The surfaces of the sinuses appeared roughened, rugose and porous due to overlying plaques of new bone. Chronic inflammation and/or infection of the maxillary sinuses frequently secondary to poor ventilation, allergy and the chronic exposure to polluted sooty air (Roberts and Manchester 1995, 131-132). This disease is particularly common in the smoggy cities of post-medieval Europe, and prevalence increased in line with air pollution associated with industrialisation. Long-term exposure to air-borne pollutants was compounded by many industrial processes, leaving industrial and manufacturing workers (eg. miners, foundry and cloth workers) at severe risk of diseases of the ears, nose, throat and chest.

A different cause of sinusitis was observed in skeleton 225. Here, a very large dental abscess had perforated the inferior aspect of the left maxillary sinus, spreading the infection into the sinus cavity.

#### Chronic respiratory disease

Respiratory disease was commonplace in the medieval period and became even more of a cause for ill health following rapid urbanisation in the later post-medieval period. From the 18th century, industrialisation led to a vast influx of rural poor into the cities. Living conditions amongst the slums of the urban working classes were poor with overcrowding in homes that were poorly heated and poorly ventilated, malnutrition and poor general hygiene being the norm. Long hours worked in factories with air-borne dust and chemicals also had a deleterious effect on respiratory health. One respiratory disease that thrived in these conditions was pulmonary tuberculosis, which became markedly more prevalent from the 17th century onwards, and by the 19th century reached epidemic proportions. Tuberculosis will be discussed more fully below.

The vast majority of respiratory diseases leave no trace on the bones. However, where a lesion (such as a bulla or abscess) is closely associated with the ribs, resorption or new bone proliferation on the visceral surface of the rib may occur

(Roberts *et al* 1998, 56). Traditionally, such lesions were associated with tuberculosis (TB) but Roberts *et al* (1998), concluded that no differential diagnosis was possible without the presence of tuberculoid lesions in other parts of the skeleton. Acute lobar pneumonia, bronchiectasis (eg in chronic obstructive pulmonary disease, such as asthma, chronic bronchitis and emphysema), and less likely, metastatic carcinoma, non-specific osteomyelitis and syphilis may all be possible causes.

New bone growth was noted on the ribs of three skeletons (573, 947 and 1007) of the unnamed sample. In the first, the lesions had healed well before death, whereas in the latter two individuals, bone deposition was active at the time of death. Although it is impossible to prove that pulmonary disease was the cause of death in these two prime adult females, it is not an improbable conclusion.

#### *Specific infections*

##### Tuberculosis

Archaeological evidence of tuberculosis (TB) afflicting humans dates back at least to the Neolithic period, but in Europe it was from the 16th century that TB increased noticeably amongst urban populations, causing 20% of all recorded deaths at that time, the greatest concentration being in London (Johnston 2003, 339). This trend continued through the post-medieval period. By the early 19th century, autopsies undertaken on the most indigent dwellers of cities such as Paris and London revealed that close to 100% of all cadavers examined had developed tubercular lesions at some time in their lives, although many had died of other causes (*ibid*). Deaths from pulmonary tuberculosis or consumption (based on the Bills of Mortality of the 18th and 19th centuries) afflicted an estimated 400-500,000 people, making it the most common cause of death in this period (Roberts and Cox 2003, 338).

Like most infectious diseases, TB was principally but by no means exclusively, a disease of poverty and urbanisation. Spread by droplet infection, the overcrowded and poorly ventilated housing and workplace conditions of these groups greatly facilitated its transmission amongst the urban poor. Greater vulnerability to the disease was noted in some occupation groups, with female textile factory workers exhibiting the highest TB rates of all occupational groups (Johnston 2003, 340).

TB is caused by the bacterium *Mycobacterium tuberculosis*, which most commonly invades lung tissue, but also may be found in the bones, the skin (where it was known as scrofula or the King's Evil), the gastrointestinal tract and the central nervous system (where it may cause tubercular meningitis). The bacteria may lie

dormant in the body tissues for many years, but may become active when the host's immunity is compromised, as occurs when an individual is diseased or malnourished.

In approximately 90% of cases, tuberculosis leaves no trace on the skeleton, and hence, osteological prevalence of the disease drastically under-represents the true pathology rates of this disease. Where bony lesions do occur, the most common locations are on the visceral surfaces of the ribs (but this may not be specific to tuberculosis), the vertebrae (in 25-50% of cases), and the hip and knee joints (Roberts and Manchester 1995, 141). New bone was present on the visceral surface of the ribs of three skeletons (see above). However, in the absence of other characteristic lesions, a specific diagnosis of tuberculosis could not be made. Three other skeletons (579, 757 and 944) showed similar rib lesions, but also displayed characteristic lytic and proliferative changes in the vertebrae. In skeleton 576, two smooth-walled lytic lesions were present on the anterior body of L1. More marked destruction of the cortical and trabecular bone of T6-9 and T12 was present in skeleton 757, but most extensive vertebral damage occurred in skeleton 944. In this skeleton, extensive resorption of the trabecular bone had caused collapse of the vertebral bodies, resulting in a right-sided kyphosis. Proliferation of bone had also caused ankylosis of the spine and fusion of the sacroiliac joint. An erosive lesion was also present on the lateral condyle of the right femur, associated with osteophytosis. In skeleton 638, several joints showed circular lytic lesions suggestive of tuberculosis. The joint surface of the left acetabulum was penetrated by a number of such lesions, whilst a large circular lesion penetrated the blade of the left ilium. Although the head and neck of the left femur were not present, similar lysis, but also osteophytosis, was noted on the lesser trochanter. The left leg and foot bones were atrophied and shortened, indicating that this insult had begun before the individual reached full maturity.

### Syphilis

Venereal syphilis was long the most serious and dreaded of the sexually transmitted diseases. The disease was first encountered in the western world in the 15th century AD, and rapidly spread across Europe (Roberts and Cox 2003, 340). By the post-medieval period, the 'great pox' or the 'French pox' (as syphilis was known in England) had become a significant health problem. Prevention of contagion using early forms of condoms, and treatments using mercury and guaiacum were largely unsuccessful (*ibid*). It was really only with the invention of penicillin in the 1930s that any serious inroad was made into control of this disease. Venereal syphilis is a

sexually transmitted infection caused by the bacterium, *Trepanima pallidum*, and is the only one of the treponematoses (a group of diseases that includes yaws, pinta and endemic syphilis) that may have a fatal outcome. Syphilis is transmitted by sexual contact or may be passed from an infected mother to her foetus. The latter is known as congenital syphilis.

Venereal syphilis acquired in adulthood is a chronic infection characterised by three clinical stages separated by latent stages with no visible symptoms (Arrizabalaga 2003, 316). In primary syphilis, a small painless ulcer or chancre appears on the genitals (and less commonly elsewhere) within 2-6 weeks of infection. In most cases, after a brief latent period, there is a secondary stage characterised by widespread lesions on the skin and in the internal organs, a painless rash, fever, malaise and bone ache. These symptoms disappear after a few weeks, but in 25% of sufferers they recur during the first two years (*ibid*). The tertiary stage only develops in a third of untreated cases, and only following a latent phase that may vary in length from 1 to more than 20 years. It is this tertiary stage that causes such profound systemic damage that results in insanity and death. The bacterium causes progressive destruction of a number of systems of the body, including the skin, mucous membranes, bones, the heart and blood vessels and the nervous system. Nervous system involvement causes a loss of positional sense and sensation that manifests as locomotor ataxia (a stumbling, high stepping gait), and bouts of insanity, which is known as general paralysis of the insane (*ibid*; Roberts and Manchester 1995, 153). Fatality from tertiary syphilis occurs through cardiovascular involvement, such as ruptured aneurysm, or cardiac valve failure.

Congenital syphilis refers to syphilis transmitted to the unborn child of a mother suffering from venereal syphilis, and occurs in 80% of pregnancies where the mother is infected (Aufderheide and Rodriguez-Martin 1998, 164). The spirochete bacteria are transmitted across the placenta to the foetus after the first 16-18 weeks *in utero*. Spontaneous abortion and stillbirth are commonly associated with the condition. Surviving infants frequently manifest with developmental anomalies, such as deafness, cusp malformations of the permanent dentition (Hutchinson's incisors and mulberry molars), interstitial keratitis, impaired cognitive development, periostitis, osteochondritis and osteomyelitis. Syphilitic infection of the scalp, historically described as 'scald head', was a very visual, unsightly manifestation of congenital syphilis.

The London Bills of Mortality attributed between 1 and 30 deaths per year to 'scald-head' in the period between 1740-1810 (Roberts and Cox 2003, 341-2). The true mortality rate of congenital syphilis was probably much higher. Nevertheless, many sufferers of congenital syphilis did survive into mature adulthood, as evidenced by skeleton 975 (a prime adult male) and skeleton 1258 (a young adult, possible female). The remaining five congenital syphilitics in this assemblage were less fortunate, with skeletons 954 and 997 dying within the first year of life; skeleton 608 and 1024 dying in childhood; and skeleton 783 surviving into later adolescence. All of the above skeletons displayed the mulberry molars characteristic of congenital syphilis, and two (skeletons 1024 and 1258) had Hutchinson incisors. Thickening of the long bone shafts and flaring of the metaphyses were present in skeletons 608 and 954. None of the seven showed the classical gummatous lesions of this condition, although periostitis was present on the femora of skeleton 783.

### *Other pathological conditions*

#### *Paget's disease*

The skeletons of 594 and 1171 showed bony changes indicative of Paget's disease. In the former, massive disorganisation and thickening of bone was present in the occipital and frontal bones of the cranial vault, the femoral and humeral shafts, and the sacrum, and vertebrae. In skeleton 1171, bony proliferation was most marked on the mandible.

Paget's disease is a condition of unknown aetiology characterised by a profound increase in both bone resorption and new bone formation resulting in simultaneous mixtures of lytic and sclerotic processes, initiating as a localised condition but often terminating as a widespread state. The clinical, symptomatic form of the disease is certainly one of older people, most commonly aged over 60 years (Aufderheide and Rodríguez-Martin 1998, 413). A famous sufferer is thought to have been Jane Austen, a contemporary of the individuals buried at St Luke's church.

In Paget's disease, there is thickening of the skull particularly at the supra-orbital margins, thickening and porosity with new bone formation of the sternal body, manubrium, and bodies of all the vertebrae. The clavicles, shafts of the humeri, ulnae, radii, femora, tibiae and fibulae are all markedly thickened and porous with areas of plaque formation and spicules. The porosity is caused by hypervascularization while the thickening, caused by abnormal osteoblastic activity is most prominent in the

femora and tibiae to the extent where the cortices appear sclerotic. All the bones are heavier than normal. The involvement of multiple bones and the thickening of the shafts due to the proliferation of new bone were consistent with Paget's disease.

#### *Aortic aneurysm erosion*

A number of lumbar vertebrae of skeleton 114 show shallow concave erosions of the left anterior aspect of the bodies. These bone changes are characteristic of the presence of an abdominal aortic aneurysm of long standing (Aufderheide and Rodriguez-Martin 1998, 78-9). An aneurysm is a weakness in the wall of an artery (in this case, the aorta), which causes localised dilation of the artery. Tearing of the inner layers of the artery wall may also occur, which enables blood and arteriosclerotic plaques (composed largely of cholesterol) to penetrate, thereby narrowing the lumen of the artery and impeding the normal flow of blood through the cardiovascular system. The abdominal aorta is anatomically located immediately anterior and to the left of the vertebral column, bound to the spine by ligaments and fascia. Pulsating of the aorta may erode the left side of the vertebral bodies, particularly where this pulsation is exaggerated, as it is with an aneurysm.

Aneurysm of the aorta is a potentially fatal condition. In addition to the impedance of blood circulation to the abdominal, pelvic and lower limb regions, the propensity of the weakened walls to rupture may result in a sudden, catastrophic haemorrhage. Aneurysm formation is associated with age, hypertension, diabetes mellitus, and elevated lipid levels. Aneurysms found in tertiary syphilis are less commonly abdominal, tending to occur in the thoracic region close to the heart (*ibid*), but may have the same fatal outcome.

#### *Cholelithiasis*

One calcified gallstone was recovered from the abdominal region of skeleton 993, an ageing female. Cholelithiasis, or gallstone formation, is a fairly common disorder in modern populations, particularly amongst middle-aged, multiparous, obese women (the so-called 'fair, fat, fertile and forties or fifties females'), where prevalence is as high as 20% (Chandrasoma and Taylor 1995, 656). Diabetes mellitus also predisposes individuals to this disorder. In 30% of individuals with gallstones, there are no symptoms, but acute or chronic cholecystitis may occur if the gallstones move from the gall bladder and block the common bile duct, resulting in biliary colic (severe intermittent abdominal pain) and nausea. Complete obstruction of the gut leads to deep jaundice and fever. Calcification of gallstones occurs only in chronic cases, and

hence, it may be assumed that skeleton 993 had suffered this condition for many years. Thus, at the time of onset she would indeed have fallen into the most common age group and sex for this condition.

### ***Congenital anomalies***

A number of congenital anomalies that would have had little or no effect on the growth, development and health of the affected individual were seen on 24 skeletons. These traits represent minor genetic variations between individuals, and loosely are

*Table 5.9 Unnamed skeletons showing the presence of congenital anomalies (n = 655)*

Sacralization	<i>Spina bifida occulta</i>	Rib anomalies	Vertebral anomalies

thought to indicate familial relationships. The congenital anomalies found in the unnamed population are listed in Table 8 below. Sacralisation (fusion of the last

lumbar vertebra to the first sacral segment) was present in 17 individuals (2.60 %). this was by far the most common anomaly. *Spina bifida occulta* was recorded in three individuals. This condition involves non-fusion of some or all of the sacral segments dorsally. Unlike *spina bifida* proper, there is no clinical sequelae to this condition, and at most, the abnormality may be marked superficially by a small tuft of hair on the lower back.

### ***Craniotomy***

The skulls of skeletons 448 (a prime adult possible male) and 1165 (a young adult male) had undergone horizontal craniotomies soon after death. It is assumed that they had been used for medical dissection prior to their interment.

In the Georgian and Victorian periods, post-mortem dissection was an uncommon procedure, and usually one over which the deceased and their relatives exercised little control. In the 18th century, there was a growing need in medical institutions to be provided with cadavers on which students might learn anatomy and practise dissection. In 1752, the Company of Surgeons was granted the corpses of all executed felons. However, demand far outstripped supply, and many additional cadavers were supplied to anatomy halls by 'resurrectionists', who raided graveyards, exhuming corpses and selling them on for a handsome profit (Porter 1997, 318). In 1829, public outrage at this practice reached a peak with the notorious case of Burke and Hare. The outcome of this outrage was the passing of the Anatomy Act (1832), in which the medical profession were permitted to take for dissection all 'unclaimed bodies' of those dying without family, or those dying in the workhouse or hospitals. As a result of the act, there was a reduction in bodysnatching, but the act also served to deepen the fear and shame amongst the poor of dying at the expense of the parish.

The antithesis to the notion of being dissected was based around religious and social perceptions. The Christian belief in the resurrection of the whole body on Judgement Day led to fears that dissection would damage the spiritual state of the dissected person. A deep-seated solicitude for the corpse causes reactions of revulsion at the indignity that the body suffered during exhumation and dissection. Particularly with regards to female corpses, the physical exposure of the naked body to the gaze of young men was perceived as harrowing, a process tantamount to sexual assault (Rugg 1999, 225).

## **Discussion**

The unnamed population of St Luke's church constitutes a large skeletal assemblage of the later post-medieval period. Useful comparisons in assemblage composition, stature and some skeletal pathologies may be made with the growing number of burial assemblages known from this period. By virtue of the low resolution methodology used, comparison between other pathology prevalences cannot be made.

From the known burial traditions of the late Georgian/early Victorian period and parish records, it was postulated that the unnamed assemblage from St Luke's church was principally composed of the working classes resident in the parish. This was in contrast to the named individuals from the church, who were largely middle class. Some skeletal and dental indicators do suggest that social differences did exist between these two groups, but these differences were not always as clearly defined as was anticipated. However, the unnamed assemblage of St Luke's church do not appear as deprived as the destitute lower working classes of the Cross Bones burial ground, Southwark.

Islington in the Georgian/early Victorian period was a gracious suburb, described by Goldsmith (in Porter 2000, 148) as a 'pretty neat town, mostly built of brick, with a church and bells', celebrated for its well or spa of health giving waters, its fine air and its high location with a magnificent panarama of the city. It was a far cry from the tangle of warehouses and slums of Southwark, and had more in common with the new modern urban developments of the West End. The working classes of Islington appeared to have benefited from the cleaner air and removed location from the factories of the East End. Although certainly not living off the fat of the land, overall the working classes in Islington do appeared to have enjoyed a better quality of life than experienced elsewhere in the metropolis. This does appear to be reflected on their mortal remains.

### **The named assemblage**

#### ***Introduction***

The skeletons of 231 named individuals buried within the precinct of St Luke's church underwent full osteological analysis. Of these, 219 (90.87%) were adult, and 22 (9.13%) subadult. The majority of this assemblage (77.56%) was located within

the crypt of the church or within extramural vaults or brick-lined shaft graves in the north and south churchyards. From these burial contexts, it would appear that the named skeletal assemblage represents the upper and middle classes buried at the church. Interesting comparisons with the unnamed St Luke's assemblage and a number of broadly contemporary burial assemblages have been made wherever possible.

Surviving *departum* plate inscriptions for this assemblage display the name, age and sex of the deceased. This provided osteologists with a rare and very valuable opportunity to evaluate the precision and accuracy of the different ageing and sexing techniques commonly employed by archaeologists against chronological age and sex. The results of these blind studies are discussed in the report.

### *Estimation of age*

Osteological assessment of age provides the biological age of the skeleton and not the chronological age. Differences between the two may occur as a result of the exposure to external factors, nutrition and lifestyle, which impact on skeletal growth and subsequent degeneration. Osteological ageing of subadults provides more narrow age ranges since the growth and maturation sequence of children is fairly predictable and uniform. The development and eruption of both deciduous and permanent dentition are also less affected by environmental influences than skeletal tissue (Roberts 1997, 111). Osteological age estimation of adults over the age of 25 relies on the degeneration of various sites on the skeleton.

In order to increase the accuracy of the assessment of osteological age in all individuals, multiple methods were used. For the subadults, one or more of the following methods were used: the formation and resorption of deciduous dentition and the formation of the permanent dentition (Moorees *et al.* 1963 a and b), length of long bones (Hoppa 1992) and epiphyseal fusion (Workshop 1980; Schwartz 1995). Epiphyseal fusion was also used for adults up to the age of around 28 years.

For the assessment of osteological age of the adults, the degenerative changes of the auricular surface (Lovejoy *et al* 1985) the pubic symphyses (Todd 1920; 1921; Suchey and Brooks 1990), and the sternal rib end (Iskan *et al* 1984, 1985) was used. Cranial suture closure (Meindl and Lovejoy 1985) and dental attrition (Roden 1997) were also used but these two methods were not as rigorously applied as the aforementioned since their accuracy generally not held to be high.

### *Sex determination*

Differences in sexual morphology between males and females emerge after the onset of puberty. Generally, sex can therefore only be determined with any degree of accuracy in individuals aged more than 17 years. Cranial, pelvic and post-cranial metric measurements are used in the determination of sex. The differences between the sexes are most pronounced in the pelvis, due to the adaptation of the female pelvis to childbirth. The female pelvis is generally lower and broader to allow for the passage of the foetal head. The male cranium tends to be more robust than the female, with pronounced brow ridges, and larger muscle attachment sites.

Post-cranial measurements rely on the generalisation that males tend to be larger than females. The measurements of the diameters of certain joints can therefore be used to determine sex. However, in both modern and past populations there are larger females and smaller males. This overlap between the sexes therefore provides a substantial zone of intermediate values where sex cannot be determined using this method alone.

Six cranial features and a maximum of ten pelvic features were used for sexing. On the cranium, the features used were those recommended by Buikstra and Ubelaker (1994). Pelvic features included the sciatic notch, the preauricular sulcus (Workshop 1980) as well as the pubic bone region (Phenice, TW 1969). The measurements used in sex determination were the diameters of the femoral, humeral and radial heads, the length of the clavicles and the width of the glenoid fossa (Chamberlain 1994).

### *Assemblage composition*

The assemblage of named individuals that underwent osteological and palaeopathological analysis comprised 241 individuals. A skeleton was classified as a named individual when it was associated with a legible breastplate. The maximum information available from the plates are the full name, age-at-death and date of death. However, an individual with a partially legible plate (for example, a surname and a year of death was discernible) was also included in the named sample. Hence, all skeletons with any biographical information were included in this group.

The majority of the named individuals had been interred within the crypt (67.22%). A further 10.37% were found within the extramural vaults in the northern and southern churchyards. The remaining 22.41% were located in earth-cut or brick-

lined graves within the northern and southern churchyard (Table 5.10). From a socio-economic viewpoint, the individuals from the crypt and the vaults (77.59%) are likely to have been more affluent and from a higher social class than the people interred in the earth-cut graves of the churchyards. In general, individuals buried within brick-lined shaft graves were typically from the middle classes (Litten 1991). The named assemblage is therefore believed to be a rather more affluent group of individuals than the unnamed assemblage.

Table 5.10 Distribution of named individuals (n = 241)

Burial location	Named individuals
South churchyard	14.94% (36/241)
South churchyard, vault	6.64% (16/241)
North churchyard	7.47% (18/241)
North churchyard, vault	3.73% (9/241)
Crypt	67.22% (162/241)
Total	100% (241)

### *Preservation and completeness*

Preservation of human remains may vary considerably between different areas within a cemetery, due to the complex interaction between a wide range of variables within the buried environment. The preservation of human remains and associated funerary paraphernalia depends entirely on the micro-environment within each grave and coffin (Henderson 1987, 43).

A number of factors affect both the preservation and completeness of a skeleton. The primary factor is the pH value of the soil. However, the depth of the burial, the degree of compression *in situ*, and the quality of excavation and post-excavation treatment will also have an effect (Brothwell 1981, 7-9). The type of burial container and the use of absorbent material, such as sawdust, bran or lime, within the coffin also affects preservation. Other factors include the age and sex of the individual, as well as various pathological conditions (such as osteoporosis). Root

intrusion, burrowing animals and sacrosaprophagous insects may also cause pseudopathologies (Wells 1967, 8-11).

Preservation and completeness were scored on a scale from 1 (poor) to 4 (excellent) during analysis. Overall, regardless of the location of the burial, 80.92% of the inhumations had a completeness score of either good or excellent and the preservation of 57.26% of the assemblage was either good or excellent (Table 5.11 ).

*Table 5.11 Completeness and preservation of the named assemblage (n = 231)*

Completeness	Number of individuals	Preservation	Number of individuals
1 (poor)	8.30% (20/241)	1 (poor)	5.39% (13/241)
2	10.79% (26/241)	2	37.34% (90/241)
3	19.91% (48/241)	3	47.30% (114/241)
4 (excellent)	61.0% 147/241)	4 (excellent)	9.96% (24/241)

Location clearly affected skeletal preservation. The highest proportion of the least well-preserved individuals (26.55%, combined preservation grades 1 and 2) was located in the crypt (Table 5.12). This poorer bone preservation is in part due to past and recent vandalism of the coffins, and in part, due to accelerated demineralization of bone salts due to the presence of sawdust within many of the coffins. The type of coffin material also influenced skeletal preservation. The advanced age of many individuals interred within the crypt may also have influenced bone preservation since conditions, such as osteoporosis, render bone more fragile, and hence, more susceptible to accelerated degradation. A relatively high number of individuals (11.62%, combined preservation grades 1 and 2) were also not very complete (Table 5.13). Loss of body parts, particularly skulls, is likely to be directly due to vandalism.

*Table 5.12 Bone preservation and burial location (n = 241)*

	1 (Poor)	2	3	4 (excellent)	Total number of individuals
South churchyard	0	9.13% (22/241)	4.98% (12/241)	0.83% (2/241)	14.94% (36/241)
South churchyard, vault	0	2.91%	2.91%	0.82%	6.64%

		(7/241)	(7/241)	(2/241)	(16/241)
North churchyard	0	2.90%	4.15%	0.42%	7.47%
		(7/241)	(10/241)	(1/241)	(18/241)
North churchyard, Vault	0	1.24%	2.49%	0	3.73%
		(3/241)	(6/241)		(9/241)
Crypt	5.39%	21.16%	32.78%	7.89%	67.22%
	(13/241)	(51/241)	(79/241)	(19/241)	(162/241)
Total number of individuals	5.39%	37.34%	47.30%	9.96%	100%
	(13/241)	(90/241)	(114/241)	(24/241)	(241)

There was little difference in skeletal preservation between those buried within in earth-cut graves or those within the extramural vaults of the churchyards. However, a higher proportion of these skeletons were more complete than those interred within the crypt (Table 5.12). This reflects the greater inaccessibility of these inhumations to vandals.

*Table 5.13 Completeness and burial location (n = 241)*

	1 (Poor)	2	3	4 (excellent)	Total number of individuals
South churchyard	0.42%	2.49%	4.15%	7.88%	14.94%
	(1/241)	(6/241)	(10/241)	(19/241)	(36/241)
South churchyard, vault	0	1.24%	0.83%	4.57%	6.64%
		(3/241)	(2/241)	(11/241)	(16/241)
North churchyard	0.83%	1.24%	1.24%	4.16%	7.47%
	(2/241)	(3/241)	(3/241)	(10/241)	(18/241)
North churchyard, Vault	0.83%	0.42%	1.24%	1.24%	3.73%
	(2/241)	(1/241)	(3/241)	(3/241)	(9/241)
Crypt	6.22%	5.40%	12.45%	43.15%	67.22%
	(15/241)	(13/241)	(30/241)	(104/241)	(162/241)
Total number of individuals	8.30%	10.79%	19.91%	61.0%	100%
	(20/241)	(26/241)	(48/241)	(147/241)	(241)

### **Demography**

Demographic profiles in living populations involve the comparison of statistics of fertility, mortality and migration patterns. The demographic analysis of past populations based on skeletal samples normally concentrates on mortality, since in the absence of historical records, fertility and migrations can only be inferred from the osteological data. The survival of burial records adds an extra dimension to the study of population structure in the post-medieval period. This allows comparison between

osteological ageing and sexing methods and the actual chronological age and sex of the individuals as recorded on coffin plate inscriptions.

For the comparison of the real age of the individuals with the osteological age, the adults with an unknown age from both categories were proportionately redistributed. The coffin inscription data has also been grouped into the same broad age categories as those used for the ageing of the skeletal remains.

#### *Osteological age and sex*

The assemblage of 241 individuals comprised 23 (9.54%) subadults and 218 (90.46%) adults (Table 14). A total of 24 adults were assigned to the broad adult category (18+ years), and have been proportionately redistributed. The osteological age indicates a gradual rise of mortality of the adults with 162 individuals (67.22%) living beyond 40 years. Of these, 101 (41.91%) were aged over 50.

Ten adults could not be sexed. These were proportionately redistributed. In addition, numbers of females and possible females, and males and possible male skeletons have been combined to produce single female and male totals. Of the adults, 55.71% were male and 44.29% (including a juvenile) were female. The proportion of males to females is slightly higher in the named than the unnamed assemblage (52.53% and 47.47%) from St Luke's church. Similarly, the former proportions are higher than the deaths listed in the London Bills of Mortality 1790-1840 (cited in Molleson and Cox 1993, 208).

The mortality rates for males still gives a gradual rise through the age categories followed by a sharp increase in the ageing adult category. The female mortality rates mirror this same curve.

*Table 5.14 Osteological age/sex (redistributed totals) of the named assemblage (n = 241)*

	Neonate	Infant 1	Infant 2	Juvenile	Young adult	Prime adult	Mature adult	Ageing adult	Total
	(0-11 months)	(1-5)	(6-11)	(12-17)	(18-25)	(26-40)	(40+)	(50+)	
?M/M	-	-	-	-	4.15% (10/241)	9.54% (23/241)	14.11% (34/241)	22.82% (55/241)	50.62% (122/241)
?F/F	-	-	-	0.42% (1/241)	3.73% (9/241)	5.81% (14/241)	11.20% (27/241)	19.09% (46/241)	40.25% (97/241)
Unknown	4.15% (10/241)	3.32% (8/241)	0.83% (2/241)	0.83% (2/241)	-	-	-	-	9.13% (22/241)
Total	4.15% (10/241)	3.32% (8/241)	0.83% (2/241)	1.25% (3/241)	7.88% (19/241)	15.35% (37/241)	25.31% (61/241)	41.91% (101/241)	100% (241)

### *Known chronological age and sex*

Of the total number of individuals classified as named, 19 were of unknown age and for comparative reasons, were redistributed proportionately. The assemblage consisted of 22 (9.13%) subadults and 219 (90.87%) adults (Table 15). The mortality trend of the adult indicates that 149 individuals (61.82%) lived to an age greater than 50 years.

Of the adult sample, four were unsexed and were redistributed proportionately. In total, 53.12% were male and 46.88% were female. The assemblage therefore consisted of 6.24% more males than females. In the neonate category (the first year of life), it is striking that 50% more females died before the age of one year than male babies. The significance of this finding is difficult to assess given the small size of the neonatal age group ( $n = 10$ ). The mortality rates of male and female children aged between 1 and 10 appear to be very closely matched. However, the death rate is strikingly higher in young adult males than females, with 50% more males dying between 18-25 years. This is surprising given the high rate of childbirth-related deaths historically known from this period. In the adults aged over 26 years, there is little difference in the mortality rates between males and females.

*Table 5.15 Known chronological age/sex (redistributed totals) in the named assemblage ( $n = 241$ )*

	Neonate	Infant 1	Infant 2	Juvenile	Young adult	Prime adult	Mature adult	Ageing adult	Total
	(0-11 months)	(1-5)	(6-11)	(12-17)	(18-25)	(26-40)	(40+)	(50+)	
Male	1.25% (3/241)	2.08% (5/241)	0.42% (1/241)	0.42% (1/241)	6.22% (15/241)	5.81% (14/241)	2.90% (7/241)	34.02% (82/241)	53.12% (128/241)
Female	2.49% (6/241)	1.66% (4/241)	0.0% (0/241)	0.83% (2/241)	2.90% (7/241)	6.64% (16/241)	4.56% (11/241)	27.80% (67/241)	46.88% (113/241)
Total	3.74% (9/241)	3.74% (9/241)	0.42% (1/241)	1.25% (3/241)	9.12% (22/241)	12.45% (30/241)	7.46% (18/241)	61.82% (149/241)	100% (241)

### *Discussion*

Overall, 23 subadults (9.54%) and 218 adults (90.46%) were identified osteologically. From breastplate inscriptions, there were 22 subadults and 219 adults. Hence, one subadult had been wrongly assigned an incorrect age. This is probably due to the actual age at death being around 18 years but skeletally the individual appeared more

immature. Indeed, skeleton 597 was aged 18 but the epiphyseal fusion age was 15-16 years and dental development 12-18 years (Table 5:13). Prolonged poor health may have affected the growth and development of this skeleton, causing delayed epiphyseal fusion, and hence, a younger osteological age estimate.

The London Bills of Mortality during the years in which the cemetery was in use demonstrate that 50% of the population died before the age of 21 (Molleson and Cox 1993, 208). In contrast, there was a very low number of subadults in the named assemblage. Of the named individuals that underwent osteological analysis, 3.74% of the children were aged younger than a year, 7.48% were aged between 0 and 5 years, and 18.27% were aged below 25 years. However, when looking at all the named individuals, including those who were reburied without any osteological analysis, 351 individuals could be aged from the coffin inscriptions. Of these, 5.98% ( $n = 21$ ) were less than one year old, and 13.96% ( $n = 49$ ) were aged between 0 and 5 years. Eighty individuals (22.79%) also died before the age of 21 years.

These figures were compared to the broadly contemporary crypt population ( $n = 357$ ) of Christ Church, Spitalfields, where 9.30% died before aged one, 19.12% were aged between 0 and five and 23% were aged below 21 (Cox 1996, 20). This indicates that both at St Luke's church, Islington, and Christ Church, Spitalfields, children are under-represented by at least 27% in the vaults and the crypt. In the latter, Cox (1996) suggested that many people from outside the parish buried their children in the parish in which they lived, despite themselves being buried in the parish of their birth. Children were therefore buried in the most convenient place (Cox 1996, 20).

This conclusion is surprising given the sentimentality surrounding infant deaths, and the emphasis placed on burial within family groups in this time period. It is however striking that the mortality rates of subadults in these two upper to middle class groups are so similar. This similarity may be explained more successfully in socio-economic terms than in terms of differential treatment of the dead of different age categories. It is probable that these rather affluent populations did indeed have a lower than average infant mortality rate for the period, due to their access to better nutrition and higher standard of living. Indeed, mortality figures compiled from nine different locations in England in 1840 highlight the great differences in child mortality rates between the classes. The average child mortality rate amongst the gentry and professionals was 20%, whereas amongst labourers, artisans and servants, the mortality rate was approximately 50% (Rugg 1999, 216). This clearly illustrates

that the mortality rates from the named sample from St Luke's are similar to those of the upper and middle classes, and probably do reflect a social reality rather than a different funerary practice or retrieval bias.

There is a striking difference between the osteologically derived and the known chronological age and sex rates for adults. In general, in the osteologically aged and sexed group, the mortality rates rose gradually with most people dying in the ageing adult group. There was no real difference between the sexes. Indeed, the only noticeable difference was that there are more males than females in the assemblage (Figure 5.4).

Trends in the known chronological age and sex mortality rates show quite a different picture (Figure 5.4). Firstly, in the young adult category there are disproportionately more males than females. This elevated level of mortality of young males is a phenomenon known as the 'trauma hump'. In modern populations, this increase is associated with deaths due to accidents. This kink is apparent in life tables for 1838-1854, but diminishes towards the end of the Victorian period (Woods and Shelton 1997, 93). Although trauma may have been a contributory factor amongst young males, the cause of death was dominated by phthisis (respiratory disease of mixed aetiology) and pulmonary tuberculosis (*ibid*, 93).

Comparatively, there are more individuals in the mature adult category in the osteologically aged group than in the known chronological age group. The main reason for this is that many adults were osteologically under-aged. Indeed, 19.91% (41 individuals) have been under-aged. The mortality rates for the individuals of known chronological age and sex clearly shows that 61.82% reached an age over 50 years. This clearly demonstrates the limitations of the ageing methods used by the osteologist. These are discussed in more detail in the next section.

### ***Evaluation of the age at death methods***

#### ***The adult population***

The age of 165 adults is known from biographical data. This allowed for the evaluation of the ageing methods. A maximum of six ageing methods were used on individuals aged over 28 years. Dental development and epiphyseal fusion were used to age adults younger than 28 years, and less frequently, diaphyseal long bone length. The results of the accuracy of these methods are discussed below. Eight (4.85%) adult

individuals were osteologically aged using five methods. The majority of the individuals were however aged using two (47 individuals, 28.49%) or three (45 individuals, 27.27%), see Table 5.16.

Table 5.16 Quantification of osteological age assessment methods used per individual (n = 165)

Number of osteological methods used						Total
Number of methods	5	4	3	2	1	
Number of individuals	8	33	45	47	32	165
% of individuals	4.85%	20%	27.27%	28.49%	19.19%	100%

The most commonly used method for ageing the adults was degenerative changes to the iliac auricular surface (Lovejoy *et al* 1985). This method was applied to 138 (83.63%) individuals (Table 5.17). This part of the pelvis most commonly survives archaeologically as the bone structure is strong. The Suchey-Brooks method of ageing from the symphysis pubis was favoured over other methods, being the most recently developed. This method was used to age 78 individuals (47.27%). Due to unusually good preservation of the sternal rib ends, degenerative changes of the sternal rib could be used for 80 individuals (48.48%). Dental attrition was analysed in 64 individuals (38.79%). The extent of ectocranial cranial suture closure was used to age 26 individuals (15.75%). Dental development was used twice and epiphyseal fusion on eleven young adults. When results of the individual osteological ageing methods are compared with the chronological ages, a number of interesting general observations could be made. Each method and the success of its application will be discussed

Table 5.17 Quantification of ageing methods used on the named adults (n = 165)

Auricular surface	Suture closure	Dental attrition	Dental development	Epiphyseal fusion	Pubic symphyses (Suchey-Brooks)	Pubic symphyses (Todd)	Sternal rib end
138	26	64	2	11	78	34	80

individually. The full summary of the age at death obtained by each method and the actual age of the individual appears in Table 5.18.

### Iliac auricular surface

When comparing the osteological auricular surface age ranges with the chronological age at death, it appears that, in general, skeleton aged between 20 and 40 are accurately aged (ie. this age range closely approximates the true age of the individual). However, in older age brackets there is a general tendency to underage the skeletons. Individuals in their 50s tended to be under-aged by as much as 15 years, and individuals in their seventies and eighties (grouped in the 60+ bracket were generally under-aged by approximately 20 to 30 years. Many of these septo and octogenarians were osteologically aged within the 40-44 age category. However, all of the individuals in the 'older than 60' category were indeed aged over 60.

### Ectocranial suture closure

This method provided a very poor correlation between the chronological age and the osteological age range. Very few osteological age ranges correlated with the chronological age. Having so many ageing adults in the named assemblage meant that in many skeletons the cranial sutures were fully fused and therefore, could not be assessed. Nevertheless, those who were aged by this method were generally under-aged by as much as 10 years.

Table 5.18 Chronological age of adults compared with biological age (The mean age for the Suchey-Brooks method has been use); n = 165.

Skeleton Number	Age at Death	Auricular surface	Cranial suture closure	Dental attrition	Dental development	Epiphyseal fusion	Pubic symphysis (Suchey & Brooks)	Pubic symphysis (Todd)	Sternal rib end

### Dental attrition

Due to the softer diet available in the 18th and 19th century, dental attrition is generally negligible within these population groups. It is therefore not possible to apply a methodology devised for prehistoric and medieval population groups (such as Miles 1962 in Brothwell (1981)). Instead, Roden's (1997) dental attrition method was used. This method was developed on a 19th century pauper population from Newcastle Infirmary, Newcastle-upon-Tyne, and was hoped to be more appropriate to later post-medieval populations. Roden's method was developed by first ageing all subadults by using the tooth formation standards by Smith (1991) and then sequenced by age. The adult dentition was then sequenced in order of increased attrition. The ageing method was then tested against the Suchey-Brooks pubic symphysis and auricular surface ageing techniques. The infirmary population group from Newcastle Infirmary was contemporary with the St Luke's assemblage, but was composed of the poor, a very different social class to the named assemblage from St Luke's church. As yet this method is in its infancy. This study aimed to test the value and applicability of Roden's ageing method in other post-medieval populations.

The method proved only accurate with young individuals in their twenties, when dental attrition is still slight. It became more inaccurate with increasing age. In general, individuals in their thirties were assigned an osteological age of 18-25 years, and individuals in their fifties and older had a dental attrition age of about 30-40 years. It is therefore clear that this method cannot be used for this type of population. It may however be accurate for skeletal assemblages comprising paupers and the lower working class in general, where diets were more coarse and dental attrition was greater.

### Pubic symphysis

Two methods of ageing from the symphysis pubis were used: the Suchey-Brooks system (Suchey and Brooks 1990) and that devised by Todd (1921a and 1921b). The Suchey-Brooks method was used more widely, and will be discussed in comparison to the method devised by Todd. The mean age for the Suchey-Brooks method was used since the ranges for the standard deviations are very large and therefore, essentially meaningless. In a few instances an age range was present. This age range was attained when different osteological age was given from right and left pubic symphysis (Table 5.18).

The Suchey-Brooks method follows the same trend as the auricular surface ageing method. Again, it appears that this method was highly accurate for younger individuals aged between 20 and 30 years. Individuals in their forties were generally under-aged by about 10 years, and older individuals who should have been aged as 'over 60' were found to be under-aged by 20 to 30 years.

The Todd method was also highly accurate in the younger age categories. Although some individuals in their forties were under-aged, in general, most were aged correctly. Indeed, the vast majority of the over fifties were accurately aged as being over the age of 50 years (the oldest category the individuals could be aged to using this method). Though fewer skeletons were aged using the Todd method, it appears that this older method is the more accurate of the two.

#### Sternal rib end

Assessment of the degenerative changes of the sternal rib end is a method not commonly used for archaeological assemblages. This is largely due to the fragile structure of the rib ends that rarely survive well archaeologically. The method specifies that the fourth rib should be used. However, due to widespread fragmentation of the ribs of skeletons from archaeological contexts, it is seldom that one can be this specific. In testing this method, a sternal rib end from the mid-thoracic region was chosen, even if it might not be the fourth rib. The advantage of this method is that individuals may be osteologically aged up to almost 80 years. Potentially, this method is very valuable in ageing older individuals beyond 60 years (the uppermost limit of all other ageing methods discussed above).

Again, the sternal rib end method proved highly accurate amongst the individuals aged between 20 and 30 years. The accuracy for those aged 30 to 50 years was still good, but a few were either over- or under-aged. Moreover, this trend continued for all the adults aged up to 80 years old. However, compared to other ageing methods, greater accuracy was attained for ageing adults. The older adults, mainly in their seventies, who were not correctly aged tended to be under-aged rather than over-aged.

#### *Discussion of the accuracy and precision of different ageing methods*

To summarise, all of the methods used have a degree of error. This is due to the fact that there is considerable individual variation in the rate that the human skeleton ages, depending on the degree of activity-related mechanical wear, environmental

influences and genetic variability. It is therefore impossible to obtain a method with 100% accuracy at all times. Using multiple ageing methods ensures a higher degree of accuracy.

Three individuals were chosen at random, and the age ranges estimated by a number of methods were plotted against the true chronological age of the individuals. To conclude, the most accurate method for ageing older adults appear to have been the sternal rib end and the least accurate method for all adults was the dental attrition method.

All methods used for this population group were very accurate when used for adults younger than 30 years old. Between 30 and 50 years, there is a high variability where methods almost appear to be somewhat hit and miss. Though some methods age an individual accurately, other tends to either over or under-age by about 10-15 years.

Skeletons are under-aged by approximately 10 years. This margin of error tends to increase as the individual gets older. This is illustrated in Figures 5.5- 5.7 where three individuals were selected as examples of the discrepancies in true age and estimated age obtained using osteological ageing methods.

#### *The subadults*

Sixteen subadults of known chronological age were aged osteologically using a combination of up to three methods (Table 5.19). The method most commonly used was dental development, which was applied to 15 (93.75%) of the children. Epiphyseal fusion was used on 13 subadults (81.25%) (excluding the 11 adults aged by this method). Diaphyseal long bone length was used on 10 subadults (62.5%). Most of the subadults were aged by using a combination of three (8 individuals, 50%) or two (4 individuals, 25%) of the above techniques.

#### Dental development

Twelve of the children were aged correctly using this method. The three of those whose true chronological age did not correspond to the osteological age were found to have been underaged by one and three years. The average ranges provided using this method were 5.28 months amongst the children aged below one year, and 2.5 years for those aged over a year.

One of the two adults aged by this method was correctly aged and the other was under-aged by two years.

Table 5.19 Subadult ageing methods used on the named sample (n = 16)

Coffin Number	Age at Death (years)	Age at Death (months)	Age at Death (days)	dental development	epiphyseal fusion	long bone length	sternal rib end
256		5	14	3-9 months	>12 months	5-8 months	
353		12			7-12 months

991		3	14	3-9 months	>12 months		
1072		6		6-9 months	9-12 months	6-6 months	
1126		10	21	7-12 months		4-6 months	
1195	3	8		20-36 months	24-36 months	24-36 months	
1218		9	28	6-12 months	>12 months	6-12 months	
1261		10		5-8 months			

### Epiphyseal fusion

Ten of the 13 individuals aged by this method were aged correctly. Two of the incorrectly aged children were under-aged by a year, and one was over-aged by two years. The average ranges given by this method was six months for those aged under a year, and 1.28 years for the children over a year old.

Of the eleven young adults (18 to 25 years) aged by this method, six were correctly aged. All but one of the five individuals aged incorrectly were under-aged. These were under-aged by between one and sixteen years. The age range average for this group was 3.8 years.

### Diaphyseal long bone length

Seven of the ten individuals aged by measurements of the unfused long bones were aged correctly. The three individuals whose assessed age was incorrect were all under-aged by two and four years. The age ranges obtained by using this method was 2.6 months for the children aged below one year, and 0.6 years for those above the age of one.

### Discussion of the subadult ageing methods used

All of the methods used to age the subadults provided impressive results with a high level of accuracy and tight age ranges. Though there was a slightly higher degree of error in the age attained by the measurements of long bones, this method produced on average the tightest age ranges for both the individuals below the age of one year and

those aged over one year. Though the assemblage is too small to be statistically valid it does suggest that the slightly elevated levels of incorrectly aged individuals is due to the tighter age ranges. This is positively correlated when looking at the dental development method. This method had the greatest levels of accuracy but the average age range was also the greatest of the three methods.

Eight of the nine incorrectly aged children were under-aged. It is interesting that overall, across all three methods, the individuals who were incorrectly aged were more likely to be under-aged than over-aged. Since in effect, these children died prematurely, they would have been unwell. They may have been ill for some time and this is likely to have caused growth disruptions of the skeleton as well as the dentition. The methods used for ageing were developed using modern collections or x-rays. Since these methods were therefore developed using healthy individuals, it is clear that the subadults of past populations are more likely to be under-aged than over-aged.

#### *Evaluation of osteological sexing methods*

As discussed in the methodology section, the osteologically assigned sex was based upon the sexually diagnostic morphological differences of the pelvis, skull and metrical measurements. All subadults and any adult individual with an unknown real and/or osteological sex were omitted from the study. Overall, 207 adults were of known sex (from *departum* plate inscriptions), and 216 individuals were sexed osteologically. Of the 207 adults of known sex, 112 were male (54.10%) and 95 (45.90%) were females. Of the osteologically sexed individuals, 92 (42.59%) were females and 113 (52.31%) were males, and 11 (5.10%) were indeterminate. In total, 15 individuals (7.24%) had been sexed wrongly. These comprised eight (3.86%) females who had been sexed as male, and seven (3.38%) males who had been sexed as females.

When examining each of the three methods used for osteological sexing the results vary depending which method is used (Table 5.20). The methods will be discussed comparatively to each other and subsequently compared with the actual sex of the individuals.

Table 5.20 Sex determination per method used on adult skeletons ( $n = 201$ )

Sex	Pelvic sex	Cranial sex	Metric sex
Female?	3.11% (6/193)	5.08% (9/177)	2.98% (6/201)
Female	38.34% (74/193)	30.51% (54/177)	40.30% (81/201)
Male?	6.22% (12/193)	7.34% (13/177)	5.47% (11/201)
Male	49.22% (95/193)	50.28% (89/177)	28.85% (58/201)
Indeterminate	3.11% (6/193)	6.79% (12/177)	22.39% (45/201)

When comparing the methods used (Table 5.20), it was apparent that the distribution of the assigned sexes varied quite considerably. Sex estimation using only the cranium had the highest proportion of probable males and females, and overall there were far more males than females. It was noted during the analysis that many skeletons had crania that appeared very masculine, although the pelves were unequivocally female.

In contrast, the metrical sex determinations have the least probable males and females but the highest proportion of indeterminate individuals. There are also far more females than males. Sex determined by the pelvic elements alone has the lowest levels of intermediate values, as well as the lowest number of probable males and probable females. There was also a more equal split between the sexes.

When comparing the sex obtained using the three methods with the combined osteological sex and the known sex of the individuals (Figure 5.8), it was clear that sex determined by differences in pelvic morphology was the most accurate method. This is unsurprising since the sexual differences in shape are due to the female pelvis being functionally adapted for childbearing. It was also clear that there was a distinct lack of sexual dimorphism between the sexes within this population group. To a lesser extent, this is apparent in the cranial sexed group, in which rather ephemeral sexually dimorphic traits created a bias towards males. This trend was also apparent in the metric sexed group, although here the data was skewed towards the females, and a large number of individuals who were sexually indeterminate.

### Stature

The stature of the named individuals was calculated using the regression formulae devised by Trotter (1970) for white males and females. Complete long bones were used in the calculation of stature. The bones of the lower limb were favoured over those of the arm as these have been shown to carry the least error.

Figure 5.9 illustrates the sexual dimorphism within the named adult assemblage. All females fell within a range of 1.49-1.72 m and males between 1.55-1.93 m. There was a slight overlap of females of a taller than average stature and males of shorter than average stature. There was a difference in mean stature estimation of 0.12 m between male and female individuals (Table 21).

*Table 5.21 Comparison between stature estimation of seven post-medieval burial assemblages in England*

Sites	Male (Mean)	Male (Range)	Female (Mean)	Female (Range)	References
St.Luke's,Islington (named)	1.70 m	1.55-1.93m	1.58 m	1.49 m-1.72 m	
St.Luke's,Islington (unnamed)	1.70 m	1.49-1.94 m	1.58 m	1.39 m-1.74 m	
Newcastle Infirmary	1.71 m	1.60 m-1.83 m	1.60 m	1.50 m-1.76 m	Nolan 1997
St Bartholomew's, Penn	1.75 m	1.45 m-1.85 m	1.60 m	1.42 m-1.83 m	Boyle 2004, 77
St Nicholas, Sevenoaks	1.73 m	1.62 m-1.83 m	1.61 m	1.49 m-1.72 m	Boyle and Keevil 1998
St George's Bloomsbury	1.72 m	1.52 m- 1.85 m	1.60 m	1.49 m-1.72 m	Boston and Witkin unpublished
Christ Church, Spitalfields	-	1.68 m-1.70 m	-	1.54 m-1.59 m	Molleson and Cox 1993
Cross Bones, Southwark	1.69 m	1.53 m-1.80 m	1.58 m	1.42 m-1.72 m	Brickley <i>et al</i> 1999
Kingston, London	1.69 m	1.54 m-1.90 m	1.60 m	1.40 m-1.75 m	Bashford and Pollard 1998

The stature ranges and the means for both males and females are comparable to other assemblages of the same time period but of various socio-economic backgrounds (Table 21). Interestingly, the named and unnamed individuals of St Luke's church were slightly shorter than the paupers of Newcastle Infirmary, particularly the females, whose range was also more narrow.

### *Summary of contemporary sites discussed in the text*

#### *a The Cross Bones Burial Ground, Red-Cross Way, Southwark, London*

The following summary is derived from Brickley *et al* (1999). Historical data suggests that the burial ground was in use for 10-30 years in the mid 19th century. Documentary evidence indicates that those buried there were the poorest members of a poor community, with 18% coming from the workhouse. Osteologically, it appeared that ill health was widespread in this population ( $n = 148$ ). Over 70% of the skeletons were subadult (under 16 years), an unusually high proportion for a normal cemetery population, but representing the high infant mortality rates recorded from documentary sources of the time. Dental caries were present on the dentition of all but eight of the individuals examined. Twelve of the 39 adults had one or more periapical abscesses. Most of the skeletons in which there was significant ante mortem tooth loss were in the 46+ age category, but some younger individuals also had significant tooth loss. There was no evidence for any type of restorative dental treatment, which is unsurprising given the poverty of the assemblage.

#### *Newcastle Infirmary, Newcastle-upon-Tyne*

The human skeletal remains from the cemetery attached to the Newcastle Infirmary, dated to between 1745-1845. These individuals could not afford to receive medical treatment in their home, and hence, were unlikely to belong to the upper or middle classes. Nor were they paupers (Nolan 1997). It is therefore safe to assume that the individuals buried here were likely to have belonged to the working class, although they were probably not destitute.

#### *St Bartholomew's Church, Penn, Wolverhampton*

The following information is taken from Boyle (2004). A total of 372 burials had been buried in a rural churchyard, and presumably therefore lived in a relatively healthy environment. In general terms, the sample population appears to have been a healthy one, in which many lived well into old age. Skeletal pathology was occasional, and this included degenerative joint disease and trauma. It is noteworthy that many of the coffin fittings were made of brass rather than iron, perhaps suggesting a degree of wealth. The statistician William Farr noted in 1840 that life expectancies in England were up to 20 years higher in rural districts compared with the worst urban areas (Woods and Woodward 1984).

Although it is traditionally assumed that burials within churchyards are generally less wealthy than those buried inside the church, at St Bartholomew's church a number of wealthy burials within elaborate triple-shell wood-lead-wood coffins were discovered within extramural vaults, presumably because there was insufficient room for burial remaining within the church itself.

From legible *departum* plates and gravestone inscriptions it was possible to identify 49 named individuals. Most of these were buried within extramural vaults and brick-lined shaft graves. Osteologically, it was evident that the later 18th and 19th century people of Penn were in good health, and generally lived well into old age. A total of 372 individuals were excavated comprising 100 males, 25 probable males, 102 females, 21 probable females, 45 adults of uncertain sex, 58 subadults (below the age of 16) and 21 for whom no osteological data was available. The last were recovered in sealed lead coffins that were not opened but reburied immediately. It is clear that the vast majority of the assemblage comprises adult individuals (314, 84.4%). This is comparable with St Luke's, Islington, where 86.4% of the assemblage were adults. Age at death ranged from newborn to 89 years. More than half of the adult assemblage was aged greater than 40 years (162 individuals, 51.6%). It is noteworthy that where age at death was known, there was a marked tendency to underage skeletons. There is no doubt that inaccuracy increased with the age of the individual. Dental wear was the least accurate method. The majority of subadults died aged greater than 5 years (39 individuals, 71%). This is marked contrast to the urban assemblage from St Luke's, Islington, where 74.4% of subadults died younger than 5 years. Standard dental recording was undertaken for all burials so the level of ante-mortem loss and the prevalence of dental disease are a true reflection of the dental health of the excavated sample. Ante-mortem tooth loss was comparable with St Nicholas' Church, Sevenoaks, Kent, but was lower than rates from London Road, Kingston-upon-Thames, and more than twice the rate at Christ Church, Spitalfields. Caries rate however was more comparable with London Road, Kingston-upon-Thames, and considerably less than St Nicholas' church and Christ Church. Very few abscesses were recorded at St Bartholomew's, London Road and St Nicholas (no data for Christ Church was available).

### *Quaker burial ground in London Road, Kingston-upon-Thames*

The following summary is based on Bashford and Pollard (1998) and Start and Kirk (1998). The interments dated from 1664-1814; 497 burials were historically documented and a total of 360 were excavated. There were 65 individuals in the subadult categories (foetal to age 17 years), and 295 in the adult categories. The Quakers presented an osteological picture of a generally healthy sample that mirrors the historical picture of a thriving, largely middle class community.

### *Christ Church, Spitalfields*

The following brief summary is based on Reeve and Adams (1993) and Molleson *et al* (1993). The excavations in the crypt unearthed c 1000 burials of which more than 400 were named, ranging in date from 1729 to 1872. Most of the individuals were of Huguenot descent, who lived in the Spitalfields area of London and had worked in the flourishing silk industry. Some were prosperous master weavers, whilst others were hard-working journeymen weavers who, together with merchants, surgeons and tradesmen, comprised the 'middling sort' of the 18th century.

### *St Nicholas' Church, Sevenoaks, Kent*

The following brief summary is based on Boyle and Keevill (1998). Work at St Nicholas' church involved near total excavation of the interior of the church along with watching briefs of various external works. The post-medieval assemblage of 192 ranged in date from 1550-1875 and comprised 55 males, 61 females, 59 adults of unknown sex, and 17 subadults. Most of the population were middle class.

### ***Dental pathology***

Dental pathology, such as periodontal disease, calculus, caries, abscesses and antemortem tooth loss (AMTL), is most commonly caused by the consumption of carbohydrates and by poor oral hygiene practices. In the post-medieval period, the consumption of cane sugar gradually increased. In the 16th and 17th centuries, sugar was an expensive and high status luxury available only to the most wealthy. However, the development of sugar plantations in the West Indies in the 18th century generated a more ready and affordable supply of the commodity to markets in Europe. Sugar consumption gradually spread down the social classes, until by the latter half of the 19th century it was available to all but the most indigent. By this time, the annual sugar consumption per capita ranged between 11.74 lb and 30.45 lb. In the early 19th

century, sugar was widely available to the middle classes, but was not yet cheap enough to be readily accessible to the lower classes. Thus, the wealthier individuals buried at St. Luke's church certainly could afford such a luxury, and paid for their pleasure with widespread dental decay, whilst the poorer individuals were less vulnerable to this new epidemic.

Thus, dental pathology serves as a useful indicator of the general health and cultural practices of this late Georgian/early Victorian population, including dietary habits and oral hygiene practices, pipe smoking and early dentistry undertaken by this population.

For the purpose of this section, the oral health of the individuals with permanent dentition only is discussed. Subadults with mixed or deciduous dentition were omitted due to the low number of individuals present. It is impossible to distinguish between those teeth lost as a result of caries, and those deliberately extracted by a tooth-puller or dentist. Table 5.22 compares the prevalence rates for dental pathology with a number of other assemblages of post-medieval date.

Table 5.22 Summary of dental pathology in adults from eight post-medieval sites in England

### *Ante-mortem tooth loss*

Although teeth were sometimes drawn electively, in anticipation of the agonies of toothache in later life, or lost as a result of trauma, most teeth were lost as a result of dental decay due to diets high in carbohydrates. Teeth may be lost by a number of processes. Calculus deposits may irritate the soft tissue and underlying bone, leading to the reduction of the bone (periodontal disease) and ante-mortem tooth loss (AMTL) (Roberts and Manchester, 1995, 45). Teeth may also be lost due to periapical abscesses secondary to caries or excessive attrition of the tooth crown. Internal lytic lesions, in which the tooth destroys itself from within, may also cause an abscess and vertical bone loss of the alveolar margin, and the subsequent loss of the tooth. Ante mortem tooth loss is regarded as a degenerative disease, in which the main contributing factors are old age and poor oral hygiene. It is no surprise that the older members of the named population suffered higher rates of tooth loss, and that where a population is old, AMTL rates are higher.

The presence of AMTL is apparent from remodelling of the dental sockets, which eventually heal over. The prevalence of AMTL was calculated by dividing the total number of teeth lost ante mortem by the number of alveolar sockets present. There was an AMTL prevalence of 36.10% in the named assemblage from St Luke's church. This compares broadly with other middle class burial populations of St Bartholomew's Church, Penn, St Nicholas' Church, Sevenoaks, the Quaker cemetery at Kingston-upon-Thames, and St George's Church, Bloomsbury. Interestingly, the largely middle class population of Christ Church, Spitalfields, suffered a much lower rate of AMTL, more similar to the rates found in the working class populations of Newcastle Infirmary and the Cross Bones burial ground, Southwark. Lower AMTL in these two groups is probably due to a lower consumption of refined sugar, and because the general age at death of the populations was younger.

### *Periodontal disease*

Periodontal disease is the inflammation of the soft tissues of the mouth, namely the gums, and/or the periodontal ligament and alveolar bone (Levins 2003, 245). Retraction of the gums exposes the vulnerable root of the tooth to attack by acidic plaques, commonly resulting in caries, abscesses and ante-mortem tooth loss. The main predisposing factor for periodontal disease is calculus build-up in the dental pockets. Periodontal disease is strongly associated with increasing age in both modern

01800

and archaeological populations. However, the aetiology is multifactorial with genetic predisposition, environment, diet and oral hygiene all playing a role in its development.

The disease may express itself as either horizontal or vertical bone loss. In the former, more than one tooth is affected, often involving the whole dental arcade. All alveolar walls are lost uniformly. This is by far the more common form of periodontal disease. In vertical bone loss, the lesion is localised around one or two teeth. This bony resorption around the tooth is irregular, and generally occurs without horizontal bone loss (Hillson 1996, 263-65).

Periodontal disease was recorded by subdividing the jaws into four quadrants, which were scored independently. The severity of the disease was scored as slight, medium or considerable, using the universally accepted standards set out by Brothwell (1981). Periodontal disease was observed in 75 (20.11%) named individuals. Thus, in both the named and unnamed assemblages of St Luke's church, periodontal disease rates are much the same; 20.11% and 20.0% respectively.

#### *Periapical abscesses*

Periapical abscesses may develop as a result of a number of pathological processes. Bacteria may enter the pulp cavity through dental caries, excessive attrition or trauma to the tooth crown. Bungled dental extractions and the transplantation of teeth from cadavers or from less fortunate living donors were also frequently associated with abscess development in the later post-medieval period. An abscess may also occur when a periodontal pocket is formed, allowing bacteria to accumulate within the pulp cavity and to track downwards to the apex of the root.

Considerable pain and inflammation of surrounding soft tissues is associated with periapical abscesses, often resolved only following dental interventions, such as extraction of the affected tooth, or drainage of the sinus via the root canal (as described by Pierre Fouchard in his 1746 treatise on early dentistry (translated by Lindsay 1946, 64-65). Alternatively, in untreated cases the continuous accumulation of pus around the root apex may become so severe that the pressure within the alveolar bone forces a hole or sinus to be created between the root apex and the jaw surface. This sinus allows the pus to drain (Roberts and Manchester 1995, 50), and frequently leads to the eventual healing of such lesions. It is at this advanced stage that the abscess is visible osteologically.

The prevalence of dental abscesses in the named assemblage from St Luke's church was calculated per dental socket present. The rate in this sample was 1.78% (87/4883), which was considerably higher than the all other post-medieval assemblages listed in Table 5.22, except for St George's Church, Bloomsbury, and the Cross Bones burial ground, Southwark.

#### *Dental enamel hypoplasia*

Dental enamel hypoplasia (DEH) manifests on the buccal surface of the tooth crowns as pits, horizontal lines or lines of pits. These features are the result of a thinning of the enamel caused by an interruption or slowing of the normal deposition of enamel during crown formation (Goodman and Rose 1990). DEH is induced by a number of metabolic insults, such as nutritional deficiency, weaning and bouts of childhood diseases lasting more than three weeks (Hillson 1996, 165-66, Aufderheide and Rodriguez-Martin 1998, 405). Unlike bone, enamel does not remodel during life, and so remains as a permanent indicator of such a stress episode in the first six or seven years of life.

In this analysis, the type and number of defect (groove, line or pit) present on each tooth was recorded. This level of detail has not been quantified for this assemblage. DEH was identified on the buccal surface of 231 out of 2249 permanent teeth (10.27%) in the named assemblage. This rate is slightly lower than St George's Church, Bloomsbury (16.35%), but considerably lower than the Cross Bones assemblage, Southwark, where 29% of teeth showed DEH. Given the destitution of so many buried at the latter, it is not surprising that individuals did suffer greater stress episodes in childhood, which were permanently recorded on their dentition through DEH.

#### *Dental caries*

Dental caries is a destruction of the enamel surface, the dentine (internal part of the tooth) and the cement (outer layer of the roots), caused by the acid produced by bacteria present in dental plaque (Hillson 1996, 269). The association of acidogenic bacteria and sugars in the diet is a well established cause of cavitations (Lukacs 1989, 265). Caries is classified as an infectious disease which usually progresses slowly, with the first sign being a white or brown opaque spot on archaeological teeth. In this assemblage, the size of each carious lesion was classified according to the universally used grading system produced by Lukacs (1989, 265). These grades are (i) pit or

small fissure; (ii) medium sized, less than half of the crown destroyed; (iii) large, more than half of the crown destroyed; (iv) complete destruction of the crown with only the roots remaining. The location of the lesion was also recorded. However, the frequencies pertaining to the location on the tooth, size of the lesions and which tooth affected are not considered here.

Caries prevalence was calculated per tooth. This included those caries filled by metal fillings but excluding lesions removed by filing of the tooth crown. Inescapably, caries rates are an approximation of the true prevalence, since it is not known how many of the teeth lost post mortem contained such lesions. The prevalence does however provide a general measure of the rate of caries within the population group. In the named assemblage from St Luke's church, the caries rate per tooth was 9.74% (219/ 2249). In comparison with the other post-medieval sites listed in Table 22, this prevalence is lower than most, with the exceptions of the burial assemblages from the Quaker cemetery in Kingston-on-Thames (5.4%), and St Bartholomew's church, Penn.

#### *Dental calculus*

Calculus consists of mineralised plaque. Micro-organisms that accumulate in the mouth after eating become imbedded in a matrix composed of proteins and the saliva and the organisms themselves. Processed sugar in the diet accelerates this process (Hillson 1996, 254-55). These plaques may mineralise to form calculus (colloquially known as tartar). There are two types of calculus: supra-gingival calculus situated above the gum line, and sub-gingival calculus that is found below the gum line on exposed roots. The deposits are commonly seen on the teeth nearest to the saliva glands (Roberts and Manchester 1995, 55). Regular brushing of the teeth removes most plaque deposits, thus preventing the formation of calculus. In the late Georgian/early Victorian periods, tooth brushing was rarely undertaken, and most cleaning (when done at all) consisted of rubbing the teeth with a cloth containing abrasive tooth powders (Hillam 1995).

The calculus rate was recorded per tooth present, and the size and position on the crown was noted, using recording criteria set out by Brothwell (1981). However, such a detailed presentation of this data is beyond the scope of this report. Calculus was identified on 46.33% of permanent teeth present. This varied in severity from slight flecks to a heavy coating covering substantial tooth surfaces. The prevalence of

calculus in the named sample from St Luke's church compared favourably to the burial assemblages of Newcastle Infirmary (55.85%) and St George's church, Bloomsbury (70.85%).

### *Dental anomalies*

A variety of dental anomalies can be found within the human dental arcade. These include impacted teeth, congenitally absent teeth (agenesis), supernumerary teeth and the retention of deciduous teeth. Ten impacted teeth, no supernumerary teeth and no retention of deciduous dentition in adulthood were present. Most commonly congenitally absent teeth are the third molars. In the named sample 117 teeth were congenitally absent.

### *Dental interventions*

Although the first dental school, the College of Dentists and of the Odonological Society, was not established until 1856, it has been estimated that about 40 dentists operated in London by 1800, and another 20 outside the capital (British Dental Association Museum display). In addition, there were many informal unregulated tooth drawers for those who could not afford the fees of a bona fide dentist. For the privileged, there was an array of dental treatments on offer at a price. These included fillings, removal of carious lesions by filing the tooth, dental implants and a variety of dentures using human, animal or porcelain teeth.

No dentures were recorded from the burials of St Luke's church. This is somewhat surprising given the large burial population, as in this period it was common to be buried wearing one's dentures, and often accompanied by a spare set, as was found in St George's Church, Bloomsbury, Christ Church, Spitalfields, and St Martin's church, Birmingham (Bateux 2003, 137).

However, the caries in six teeth had been filled. During the 18th and 19th centuries, the cheapest form of fillings was either tin or lead. From the beginning of the 19th century, various forms of amalgams became available. These were based on heavy metals such as mercury that was mixed with copper or silver filed from coins (British Dental Association Museum display). Pellets of the amalgam were placed in the cavity and tamped down with a hot instrument. Gold fillings were the most suitable material but also the most expensive. A typical dentist's fees of 1781 advertised gold fillings at seven shillings and sixpence, whilst lead fillings cost five shillings each (Wilson 1985, 38).

### ***Skeletal pathology***

Unlike the unnamed population, the named skeletons were formally analysed for pathology. Like many other post-medieval populations, the prevalence of skeletal pathology was very high. This is summarised in Table 5.23 below.

#### ***Congenital disorders***

##### **Congenital dislocation of the hip**

Congenital dislocation of the hip, or congenital acetabular dysplasia, is a developmental defect in which the acetabulum or hip socket is abnormally shallow and the upper margin has a smooth edge due to the tendency of the joint to dislocate. Degenerative arthritis is commonly associated with this condition, with extensive osteophytosis of the acetabulum and femoral head being common (Roberts and Manchester 1995, 38). In some cases, a false acetabulum develops superiorly on the iliac bone. An individual afflicted with the condition would experience considerable pain and difficulty in walking. A young adult female named Matilda Gibson (skeleton 970) had bilateral congenital hip dislocation. The right hip was ankylosed and immobile but the left hip joint appeared to have been used.

##### **Tapes equinovarus or club foot**

One mature adult male skeleton (skeleton 888) showed abnormal morphology of the bones of the right foot typical of club foot. All the tarsals were ankylosed, and there was malalignment of the bones superio-inferiorly rather than their usual relative position of mediolateral rows. The anterior part of the foot would have been held inverted. It is probable that this foot deformity was congenital, but traumatic damage to the bones was not ruled out (although no fractures were observed macroscopically).

Clubfoot is a fairly rare condition in modern populations, and probably was similarly rare in the past. It is a problematic disorder to recognise osteologically, and is probably very under-reported in skeletal populations (Roberts and Manchester 1995, 38).

##### **Scoliosis**

Two named skeletons from St Luke's church suffered from scoliosis. Scoliosis is the abnormal curvature of the spinal column to the left or right in the coronal plane. It differs from kyphosis, which is the abnormal curvature in the antero-posterior plane (colloquially known as a hunchback). In skeleton 723, there was lateral deviation from the midline in T3 to T9. The spinal column of Mary Lockin (ageing skeleton

860) showed marked deviation to the right in the upper lumbar region (L2), and to the left at the level of T12. T3 and 4, L1 and 2, and L3 and 4 were fused together. The ribs were modified in shape to accommodate this abnormal curvature. The internal organs, particularly the lungs, would have been compressed on the right side, possibly causing respiratory problems as well as an increased risk of blockages in the intestines. This type of spinal deformity may be caused by trauma (Aufderheide and Rodriguez-Martin 1998, 66-67), but the severity of the deformity in this individual, and the morphological changes to the ribs indicate that the scoliosis was congenital.

#### Os acromiale

During normal development, the acromial process begins to fuse to the scapula at approximately 10-14 years (Schwartz 2000). In some adults, non-union persists into adulthood, and is known as os acromiale. Originally believed to be a developmental anomaly, work on skeletons from the ship the Mary Rose, which sank off the coast of England in 1545 AD, suggests an occupational role in the development of this condition (Roberts and Manchester 1995, 113). In this assemblage, 13.6 % had os acromiale, in comparison with modern dissection room frequencies of 8.0 %. The highest frequency was found amongst skeletons found where archery equipment was stored, suggesting that prolonged archery practice from childhood was a factor in aetiology of this condition.

A mature and an ageing male (skeletons 723 and 1203) had this disorder. In the former only the left scapula displayed this anomaly, whereas in the latter individual both scapulae were involved. It is unclear how much genetic variation or repetitive arm movements sustained from childhood into adulthood underlay the development of this condition. In a society where child labour was commonplace, it is not improbable that repetitive arm motions enacted over many years of childhood, adolescence and adulthood (for example, weaving or minding a machine) caused or contributed towards this condition.

#### Other congenital abnormalities

Two skeletons had developmental defects of the spine. In ageing adult skeleton 1131 the neural arch of the atlas had not fully closed, leaving the neural canal open. In skeleton 777, the transverse process of T2 was underdeveloped. The inferior articular facets were also abnormal, being split in two. In skeleton 619, it was the right maxillary sinus that was bipartite. The extent to which these anomalies impacted on

the health and wellbeing of these individuals is difficult to surmise. However, no degenerative changes were present to indicate pathology.

### Trauma

#### Fractures

Thirty-nine named individuals showed fractures indicative of trauma. All fractures were found on adult skeletons, with twice the number being male (males, 26%; females, 13%).

Fractures may be defined by their nature and their anatomical alignment relative to the long axis of the bone. In the named assemblage, eight individuals showed oblique fractures, four showed depressed fractures of the cranial vault, two individuals had compression fractures of the vertebral bodies, and one showed transverse fractures of two proximal foot phalanges. The types of fractures on a further 24 skeletons could not be identified without the aid of radiography, largely due to callous formation obscuring the line of the fracture. These fractures were located mainly on the ribs and the smaller bones of the hands and feet. Fracture of the ribs is due to a direct blow to the chest, and occurs most commonly as a result of interpersonal violence and falls. Depressed fractures of the cranial vault have a similar aetiology. These involved three males and one female.

Oblique fractures were located peripherally, with five (skeletons 162, 522, 845, 1145 and 1208) located on the lower legs, one on the femur (skeleton 1065), one of the humerus (skeleton 859), and one Colles fracture of the distal radius (skeleton 1177). The distal radius is the second most common location of fractures associated with osteoporosis, where even a slight fall onto an outstretched arm may result in fracture of the porous bone. Given the advanced age and the sex of Celia Boyle (skeleton 1177), it is probable that her fracture was secondary to osteoporosis.

Compression fractures of the vertebral bodies were found in two individuals (skeletons 114 and 343). Crush or compression fractures result when a sudden excessive force is applied to the bone (Ortner and Putsch 1981, 56), and the bone is compressed along the plane of impact (in this instance vertically), either collapsing the body uniformly, or forming a wedge-shaped vertebral body. Crush fractures often occur where there is already an inherent weakness of the bone (most commonly due to underlying osteoporosis, but also present in pathologies such as tuberculosis or

metastatic carcinoma). In skeleton 343 new bone formation on the ribs suggests that the crush fracture of L4 in this skeleton may be tuberculoid in origin.

In severe compression fractures, the uneven collapse of the bodies precipitates a misalignment of the spinal column (scoliosis or kyphosis), which may result in compression of the spinal nerves, causing chronic pain and disturbance of sensation to the peripheries of the body. In skeleton 114, ankylosis and crush fractures of the bodies of vertebrae T5-T10 resulted in a mild kyphosis. The underlying condition afflicting skeleton 114 is unclear, but was either or both ankylosing spondylitis or severe osteoarthritis.

*Table 5.24 Prevalence of fractures in the named assemblage (n =219)*

	Male	Female	Total
Adults	22% (26/118)	12.87% (13/101)	17.81% (39/219)
Subadults	0	0	0

#### Soft tissue trauma

Enthesophyte formation was noted on six adult skeletons of the named assemblage (2.74%). Enthesophytes occur when there is ossification of the tendons and ligaments at their point of insertion onto the skeleton. This ossification is typical in some pathologies, such as DISH, but most commonly occur as a result of tears to the muscle fibres due to overuse or trauma.

*Table 5.25 Prevalence of enthesophytes in the named assemblage from St Luke's church (n =219)*

	Male	Female	Total
Adults	3.39% (4/118)	1.98% (2/101)	2.74% (6/219)
Subadults	0	0	0

#### Dislocation of the shoulder joint

Chronic dislocation of the left humerus was present in adult male skeleton 890. The humerus had become totally displaced inferiorly, and a new false shoulder socket had formed as a result of prolific osteophytosis. The shoulder joint is probably the most common joint to be dislocated through trauma, being shallow, which allows free

movement of the arm (Roberts and Manchester 1995, 87). Frequently the dislocation either is reduced spontaneously, or may be fairly easily (albeit painfully) manipulated back into its correct position. However, this did not occur with skeleton 890, who would have suffered considerable pain and reduction in function of the left arm for many years.

#### Osteochondritis dissecans

Osteochondritis dissecans is a fairly common osteological disorder found on the joint surfaces of the major long bones. Physically active young males (such as athletes) are most often affected in the first two decades of life. This disease is due to a significant localised obliteration of the blood supply, causing necrosis of small areas of joint tissue (Roberts and Manchester 1995, 87). Repeated, low-grade, chronic trauma or micro-trauma is thought to play a role in this injury to the blood vessels. The necrotic bone plaque breaks off from the joint surface and may remain loose in the joint, causing chronic pain and often precipitating osteoarthritic changes. Alternatively, the fragment may reattach in its original position or be resorbed, and no further symptoms will be experienced.

Three male adults of the named assemblage from St Luke's church (skeletons 701, 1078 and 1223) showed evidence of this disorder.

#### *Neoplastic disease*

##### Button osteomas

Five skeletons (122, 772, 777, 846 and 1145) of the named assemblage of St Luke's church had a button or ivory osteoma on the cranial vault. Skeleton 122 and 772 had a single lesion on the frontal bone, whilst skeleton 777 had one on the right parietal, and skeleton 846 on the occipital bone. Skeleton 1145 had two button osteomas: one on the frontal bone and one on the right parietal. All but skeleton 777 were mature to ageing adults. Button osteomas are small circular lumps on the ectocranial surface of the cranial vault, most commonly on the frontal bones. They are benign tumours of no clinical significance (Roberts and Manchester 1995, 188). They are more commonly found in males. Frequency rises after the fourth decade of life (Aufderheide and Rodriguez-Martin 1998, 375), as was the case in four of the five skeletons above.

Table 5.26 Prevalence of button osteomas in the named assemblage from St Luke's church (n =219)

	Male	Female	Total
Adults	1.70% (2/118)	2.97% (3/101)	2.28% (5/219)
Subadults	0	0	0

### Malignant neoplasms

Two skeletons (469 and 973) showed lesions characteristic of malignant neoplasms, which ultimately may or may not have caused their deaths. Thomas Tribe (skeleton 469) was suffering from a large lytic lesion in the left eye orbit, which had caused considerable destruction of the orbit and the nasal cavity (Plate 5.X). The diagnosis of a lytic metastatic carcinoma was made. The location of a primary tumour was not made elsewhere on the skeleton and probably involved the soft tissues only. A craniotomy was performed on Thomas Tribe following his death. This is discussed more fully below.

Table 5.27 Prevalence of malignant neoplasms in the named assemblage from St Luke's church(n =219)

	Male	Female	Total
Adults	0.85% (1/118)	0.99% (1/101)	0.91% (2/219)
Subadults	0	0	0

A mature adult female, Mary Robinson (skeleton 973) had lesions that were neoplastic in nature, but a differential diagnosis between multiple myeloma and osteolytic metastatic carcinoma could not be made.

### *Metabolic disorders*

#### Acromegaly

The skeleton of John Farmer (skeleton 967) showed bone changes indicative of acromegaly. The skull had very pronounced supraorbital ridges, and the bones of the face and mandible were enlarged, giving the face an elongated, flattened appearance. Deposition of new bone on the mandible, particularly around the mental eminence, was very marked, generating prominent prognathism. The long bones of the hands

appeared slightly thickened and the terminal digits showed 'tufting' typical of this condition.

Acromegaly is caused by an excessive production of growth hormone in adulthood, most commonly generated by a tumour of the pituitary gland. Where this occurs before full adulthood is reached, gigantism results, and the individual becomes excessively tall, but in proportion. When a tumour develops after the epiphyses of the long bones have fused, no change in stature can occur. Indeed, John Farmer stood only 162.6 cm (or 5 foot 3 inches) tall. Bone growth occurs in the flat bones, most commonly in the face, particularly the mandible, but thickening of bone does occur in the vertebrae and hand bones. The bony changes observed on the skeleton of John Farmer are very characteristic of this rare disease. Although the lifespan of modern treated acromegals is not significantly shortened by the disease, earlier cases are reported to have had substantially shortened lifespans. It is assumed that this was the case in the more distant past. John Farmer lived into his forties.

#### Cribra orbitalia and porotic hyperostosis

Cribra orbitalia is widely thought to occur in response to a deficiency of iron during childhood, most commonly the result of inadequate dietary intake of iron, and/or as a result of severe intestinal parasite infestation (Stuart-Macadam 1991, 101). Iron is a central component of haemoglobin, the molecule necessary for the transportation of oxygen in the red blood cells of the blood. Red blood cells are produced within the red bone marrow of a number of bones of the body, which include the diploe of the cranial vault, the sternum and the pelvis. In childhood, the diploe are particularly important, but become a secondary site of red blood cell production later in life. In iron deficiency anaemia, the body attempts to compensate for low serum iron levels by hypertrophy of these bones. In children, this manifests osteologically as an increased porosity and thickening of the diploe of the cranial vault (known as porotic hyperostosis) and of the orbital sockets (Cribra orbitalia). Cribra orbitalia is often used as a generic indicator of physical stress in childhood.

Twenty-three skeletons (9.54%) showed bony changes in the eye orbits consistent with cribra orbitalia. These lesions were graded in severity, using the standards set out by Stuart-Macadam (1991, 101-113). There was wide variation in the severity of the disease, with six graded as 1 (mild), five as 2 (slight), eight as grade 3 (moderate) and one as marked (grade 4).

Table 5.28 The prevalence of *cribra orbitalia* in the named assemblage (n =241)

	Male	Female	Total
Adults	5.93% (7/118)	8.91% (9/101)	8.67% (19/219)
Subadults	(10.0%) (1/10)	25.0% (3/12)	18.18% (4/22)

Porotic hyperostosis, manifesting as thickening and pitting of the left and right parietal bones, was present in ten adult individuals (4.15%). In all but one the lesions had healed.

Table 5.29 Prevalence of porotic hyperostosis in the named assemblage (n =241)

	Male	Female	Total
Adults	6.78% (8/118)	0.99% (1/101)	4.10% (9/219)
Subadults	10.0% (1/10)	-	4.54% (1/22)

### Rickets

Anterior-posterior bowing of the femoral shafts and/or medio-lateral bowing of the tibiae diagnostic of rickets was observed on 11 adults and 4 subadults in the named assemblage (6.22%). Rickets is a deficiency disease caused by a lack of vitamin D. Vitamin D is central to the absorption of dietary calcium. A deficiency results in soft, thin bones. Weight-bearing during crawling and walking in childhood cause the long bone shafts of the arms and legs to bow. Although Vitamin D may be obtained in foodstuffs such as oily fish and animal fat, the majority of vitamin D is formed by the exposure of the skin to ultraviolet radiation. The presence of rickets usually indicates an individual who had not received sufficient exposure to sunlight in early childhood.

Rickets was fairly uncommon in pre-industrial and rural agrarian societies (Ortner and Putschar 1981, 274), but became widespread in the industrial cities of the later post-medieval period. The smog that blanketed the great manufacturing centres (including London) for much of the year served to block out a great deal of sunlight. Long hours of child labour in factories and mines also ensured that many working class children were not exposed to sufficient daylight necessary for the adequate

production of vitamin D. In 1773, Fordyce (quoted in Roberts and Cox 2003, 309) estimated that 20,000 poor children in London were afflicted with this disease. The scale of the disease was still vast in the mid-19th century, with a third of all admissions to Great Ormond Street Hospital in London being diagnosed as rachitic.

However, rickets was not necessarily the sole preserve of the poor. The 17th century physician Francis Glisson (the first to describe rickets in precise clinical detail) observed that it was a disease of children of the wealthy classes, where it was common practice not to be suckled by one's natural mother, but by a wet nurse (Sloan 1996, 44). This practice usually resulted in early weaning onto gruels high in calories but poor in animal fat, and hence, low in vitamin D (Steinbock 2003a, 281-282). This social practice, coupled with keeping the young child indoors for long periods, resulted in a child from a privileged background developing the disease.

*Table 5.30 Prevalence of rickets in the named assemblage (n = 241)*

	Male	Female	Total
Adults	5.08% (6/118)	4.95% (5/101)	5.02% (11/219)
Subadults	20.0% (2/10)	16.67% (2/12)	18.18% (4/22)

### Osteoporosis

Osteoporosis is a proportional decrease of both the bone mineral and the bone matrix, leading to bone which is light and brittle, and liable to fracture after minimal trauma (Steinbock 2003, 236). There are two types of osteoporosis: Type 1 or post-menopausal osteoporosis (affecting women over 50 years of age), and commonly the underlying condition in vertebral crush fractures and fractures of the distal radius; and Type 2 or senile osteoporosis, which affects both males and females over the age of 60 years equally, and predisposes individuals to vertebral wedge fractures and fractures of the femoral neck (ibid). A drop in oestrogen levels following the menopause accounts for 10-20% loss of total bone mass in modern women (ibid). This often serves to aggravate a pre-existing negative calcium balance caused by a poor dietary calcium intake and/or the net bone calcium lost during the reproductive years through multiple pregnancies.

Table 5.31 Prevalence of osteoporosis in the named assemblage (n =118)

	Male	Female	Total
Adults	0.99% (1/118)	0	0.99% (1/118)
Subadults	0	0	0

Osteoporosis was noted in one ageing male skeleton (1157). Osteoporosis is difficult to recognise macroscopically, and it is certain that the true prevalence of this disorder in the named assemblage from St Luke's church was much higher.

#### *Joint disease*

##### Ankylosisng spondylitis

Ankylosisng spondylitis was identified on skeletons 114 (John Bailey, a prime adult male) and skeleton 1208, an ageing female named Sarah Wilcox. The lesion noted on John Bailey's skeleton is characteristic of the disease, with fusion of the sacro-iliac joint, and of adjacent thoracic and lumbar vertebrae L1 and 2, T5-T10, and T3 and 4. A slight kyphosis had developed in the region of T5-10. Enthysophyte development present on the skeleton was more typical of DISH than ankylosing spondylitis, but the ankylosis of the sacro-iliac joint and the appearance of the spinal osteophytes made the latter diagnosis more probable.

Ankylosing spondilitis is a systemic, non-infectious, progressive inflammatory disorder of connective tissue calcification (Roberts and Manchester 1995, 118-120; Aufderheide and Rodriguez-Martin1998, 102). The aetiology of the disease is poorly understood, but there appears to be a strong autoimmune causation. AS is a rare disease affecting only about 1 in 2000 individuals, 90% of which are male (ibid).

The sacro-iliac joint, spine and major peripheral joints are most frequently involved. The disease process usually begins in early adulthood, classically beginning with erosion, new bone growth and ankylosis or fusion of the sacro-iliac joint and calcification of associated ligaments. Skeleton 114 suffered from such ankylosis of the sacroiliac joint and osteophytic projections from the left auricular surface. Typically in ankylosing spondylitis, the lower thoracic/upper lumbar vertebral bodies and small vertebral joints begin to fuse, and the intervertebral disks and longitudinal ligaments ossify. This process progresses up and down the spinal column (but more

CLP00

typically the lumbar vertebrae are first to fuse), creating the classical 'bamboo spine' of this disorder.

Depending upon the extent of the ankylosis, sufferers of this disorder experience lower back pain, limited chest expansion, immobility, weight loss and fever (Roberts and Manchester 1995, 119).

#### Diffuse idiopathic skeletal hyperostosis (DISH)

As its name suggests, DISH is a systemic disorder where additional bone is deposited around a number of joints of the body. This is largely due to the ossification of surrounding ligaments. Typically, DISH begins with ankylosis of the mid-thoracic spine, due to the ossification of the anterior longitudinal ligament and paraspinal tissues. This produces a dripping candle wax appearance along the right side of the bodies of the vertebral column (Roberts and Manchester 1995, 120). This ankylosis extends superiorly and inferiorly along the vertebral column, leading to the gradual and complete fusion of the spine. Most common extraspinal sites to be affected are the sternal rib ends (where the costal cartilage ossifies) and enthesophytes at ligament and tendon attachment sites at many sites on the skeleton. The underlying cause of DISH is not clearly understood, but appears to be associated with obesity and diabetes mellitus. The disorder manifests clinically as pain, aching and stiffness in the affected joints (ibid).

*Table 5.32 Prevalence of DISH in the named assemblage (n = 219)*

	Male	Female	Total
Adults	1.69%	2.97%	2.28%
	(2/118)	(3/101)	(5/219)

Five cases of DISH were identified in the named assemblage from St Luke's church (2.28%). Of these, two were ageing males (skeletons 616 and 951), one a mature possible female (skeleton 778) and two were ageing females (skeletons 254 and 920). The ages of these individuals is consistent with the modern average age of onset of the disease, which is from 50 years onwards. These individuals exhibited the classic dripping candlewax osteophytes and ankylosis of the thoracic vertebrae, and marked enthesophyte formation at ligament and tendon insertion sites on diverse bones of the postcranial skeleton (Plate 5.3).

Table 5.32 shows the prevalence of DISH in six post-medieval burial assemblages. It is interesting to note that the rate of DISH amongst the unnamed population from St Luke's is significantly lower than that in the named assemblage. DISH in the former population more closely approximates to the prevalence found in the Newcastle Infirmary and St Bride's Lower Churchyard assemblages (both predominantly working class populations), and is considerably lower than Christ

*Table 5.33 The prevalence of DISH in five English post-medieval assemblages (figures taken from Roberts and Cox 2003, 311); WC = working class, MC = middle class*

Site name	Total No	Affected	CPR%	Class
St Luke's, Islington (named)	219	5	2.28	Mostly MC
St Luke's, Islington (unnamed)	655	8	1.22	Mostly WC
St Bride's lower churchyard	533	10	1.88	WC
Newcastle Infirmary	189	2	1.06	WC
Christ Church, Spitalfields	968	56	5.79	Mostly MC
Kingston-upon-Thames	360	3	0.83	MC
<b>Total</b>	<b>2924</b>	<b>84</b>	<b>2.87</b>	

Church, Spitalfields, where DISH was found in numbers far exceeding other sites of the period. These different rates may well reflect the differences between the diet and lifestyle of the urban working and middle classes of the period.

Historical accounts suggest that the diet of the middle classes during the 18th and 19th centuries was high in animal proteins and fats. Meat and alcohol were consumed in large quantities (Roberts and Cox 2003, 313). A wide variety of fruits and vegetables was also available, albeit seasonally. Sugar was consumed in large quantities by 19th century. The descriptions of the food served at dinner parties, and written descriptions of the daily menus suggest that overindulgence was commonplace (Cox 1996, 50-57). The diet of the working classes was very different from the upper and middle class diets. Malnutrition, particularly amongst children and women was commonplace, the majority of the common diet consisting of potatoes and bread, with little protein, fresh fruit or vegetables. Poor harvests and the subsequent rise in the price of grain occurred sporadically throughout this period, leaving the urban poor vulnerable to extreme privation, if not starvation in bad years. Thus, it is not surprising that the prevalence of DISH (a disease linked to corpulence

and over-indulgence) was more common amongst the more privileged classes than amongst the poor of Georgian and Victorian England.

### Rheumatoid arthritis

Rheumatoid arthritis is a disease of the synovial membrane of the joints that become infiltrated with inflammatory cells, causing it to become thickened and vascular (Rogers and Waldron 1995, 56). Chronic inflammation of the synovium causes outgrowths of the membrane, which gradually grow over the cartilage of the joint surface, progressively destroying it. Eburnation of the joint surfaces follows the cartilaginous erosion. As the disease progresses the joints become deformed, swollen and may dislocate. End stage rheumatoid arthritis is extremely painful and disabling, with crippling deformities most commonly of the hands and feet, but sometimes also involving the wrist, knee, cervical spine, shoulder, subtalar joint, elbow and hip (ibid).

The aetiology of the disease is poorly understood but it does demonstrate many features of an autoimmune nature (ibid; Auferheide and Rodriguez-Martin 1998, 99). It affects approximately 1% of the total modern population, with women being affected three times more often than men. It is uncertain whether this prevalence has changed over time. A famous sufferer contemporary with the St Luke's burial assemblage is thought to have been the poet Samuel Taylor Coleridge, whose attempts to deaden the severe pain of his disease with laudanum led to his famous addiction to opium and the penning of such masterpieces as 'Kubla Khan'.

An ageing female (skeleton 860) of the named assemblage of St Luke's church showed the erosive lesion characteristic of the disease on the proximal interphalangeal joint of digit three of the left and right hands. A second possible sufferer of the disease was an ageing male (skeleton 616). His left and right hands showed bilateral joint disease involving eburnation and lytic lesions on the joint surfaces of three proximal phalanges on each hand. It was not possible to confidently differentially diagnose these lesions from osteoarthritis.

### Degenerative joint disease

Degenerative joint disease (DJD) is by far the most common joint disease found in skeletal populations, and the named assemblage of St Luke's church was no exception. DJD occurs where there is damage to a joint through overuse (repetitive activity-related trauma) or through general wear and tear of the joint through life. These bone changes are often progressive and hence, correlate closely to the age-at-

death of the individual, and on a palaeodemographic level, prevalence of DJD relates to the age-distribution of the population under study.

Degenerative changes manifest skeletally as the deposition and/or resorption of bone of the joint surface. Deposition of new bone (or osteophytosis) on or around the joint surface occurs as a compensatory attempt by the body to spread the load by increasing the joint surface area. Where osteophytosis becomes severe, the new bone may cause the joints to fuse together or ankylose. This is most commonly found in the vertebral bodies. When the cartilage overlying the bone at joints is destroyed, the bone may become very dense or sclerotic. Friction between the two bones may cause polishing or eburnation. Bone resorption often occurs concurrently with bone deposition. Macroscopically, this manifests as porosity of the joint surface. Infiltration of these pores by synovial fluid may cause subchondral cysts to develop, readily visible by radiography, but less obvious to the naked eye (Roberts and Manchester 1995, 112-114).

DJD is an umbrella term describing a number of degenerative joint diseases (including osteoarthritis, rheumatoid arthritis, and psoriatic arthritis) that do not manifest specifically enough to allow for a differential diagnosis. The vertebrae are the most common location for DJD, and this pathology has been listed separately as spinal degenerative joint disease or SDJD in Table 5.43 below. In addition to the osteophytosis, porosity and eburnation described above, Schmorl's nodes are another skeletal indicator of degenerative changes of the spine. Schmorl's nodes are depressed areas on the anterior and superior aspects of the vertebral bodies where the intervertebral disc contents have herniated and have exerted pressure on the vertebral body. In modern humans, Schmorl's nodes are very common in individuals aged 45 years and more, and are generally held to have few clinical effects (Aufderheide and Rodriguez-Martin 1998, 96), although recent work does suggest that back pain frequently does accompany modern sufferers.

Seventy-eight skeletons in the named assemblage were afflicted with non-spinal degenerative joint disease (32.37%). SDJD was found in 124 adults (51.45 % of the total population, or 56.62% of the adult population). Schmorl's nodes were found on the vertebral bodies of 68 individuals (28.22%). Overwhelmingly these changes were located in the middle to lower thoracic region, and to a much lesser extent in the upper lumbar region. The high prevalence of these degenerative changes

is closely related to the age distribution of the named assemblage, in which the older age categories predominated.

### Osteoarthritis

Osteoarthritis is the most common degenerative joint disease in both humans and animals, affecting 90% of modern people over aged 40 years (Denko 2003, 234-236). In its mildest form, osteoarthritis is not symptomatic, but approximately 30% of those showing clinical evidence of the disease do experience joint stiffness and chronic pain (Denko 2003, 235). These symptoms may become severely debilitating, greatly affecting the sufferer's quality of life, activities and earning potential.

In accordance with the recommendations of Rogers and Waldron (1995), osteoarthritis was diagnosed on joints of the named assemblage where eburnation was present, and/or where at least two other features of osteoarthritis were present (namely porosity, osteophytosis or Schmorl's nodes). Osteoarthritis affected 66 skeletons in the named assemblage (27.29%). This high prevalence of degenerative joint disease and osteoarthritis is probably due to the older nature of the St Luke's named population. It is doubtful given the probable middle class composition of the assemblage that occupational stress from manual labour played a large role in the development of the disease. The location of osteoarthritis on the skeletons correlates with the general distribution of osteoarthritis seen in many past and present populations, where the major weight-bearing joints experience the greatest physical stress (Rogers and Waldron 1995, 6). The joints most affected were the spine, hips, knees and toe joints of the feet (particularly the big toe). Osteoarthritis was also identified on the wrist joints and finger joints of 11 of the named population.

### *Infection*

#### Non-specific infection

In the vast majority of archaeological skeletons, the specific bacteria responsible for bone infection cannot be identified, and is referred to as 'non-specific' infection. Bone tissue's response to infection involves both resorption and proliferation. Inflammation of the periosteum, or periostitis, manifests osteologically as new bone formation on the surface of the bone. Penetration of infection deeper into the compact bone stimulates further osteoclastic activity, leading to noticeable thickening and sometimes, distortion of the bone. This is known as osteitis. Where the infection penetrates into the marrow cavity, resorption causes pitting and thinning of the

cortical bone and an enlarged marrow cavity. The pressure of accumulated pus of this abscess may cause this debris to burst through the thinned cortical bone, creating a smooth-sided sinus or cloaca (Roberts and Manchester 1995, 126). The pus is then discharged into the overlying soft tissue, spreading the infection further afield.

*Table 5.34 Prevalence of periostitis in the named assemblage (n =241)*

	Male	Female	Total
Adults	18.64% (22/118)	14.85% (15/101)	16.89% (37/219)
Subadults	-	8.3% (1/12)	4.54% (1/22)

In the named assemblage of St Luke's church, 37 individuals showed evidence for periostitis. Rib lesions were noted on 12 skeletons and are discussed below. By far the most common location of the rest of these infective lesions was the tibial shafts, found in 20 individuals. This is perhaps not surprising, when one considers the lack of soft tissue overlying this bone, particularly on the anterior aspect, and the greater exposure of the lower leg to traumatic insults. In addition, severe peripheral vascular disease (common in the elderly, those with atherosclerosis and diabetes mellitus) often result in arterial and venous ulcers of the feet and lower legs that are notoriously slow to heal, and vulnerable to secondary infection. Spread of infection did occur in many cases, most commonly to the fibula, but also to the femur and calcaneus. In most cases, the lesions were either fully or largely healed, showing lamellar and smooth bony plaques. Other commonly affected bones were the fibulae and the femora.

Four individuals showed evidence of osteitis. Lesions were located on the femoral shaft in two skeletons (831 and 1069), on the tibial shaft in one individual (skeleton 916) and on the proximal ulna shaft of skeleton 1078. Thickening of the bone shafts due to reactive bone proliferation was present in these bones.

*Table 5.35: Prevalence of osteitis in the named assemblage (n =241)*

	Male	Female	Total
Adults	1.69% (2/118)	2.97% (3/101)	2.28% (5/219)
Subadults	-	-	0/22

Osteomyelitis is the most severe form of bone infection, penetrating to the marrow cavity. The capacity of the body's immune system to mount a defence against this infection is severely hampered by the relatively small blood supply to bone tissue. Even today, in an era of sophisticated medical care and antibiotic treatment, osteomyelitis remains one of the most difficult infections to treat. In the named assemblage of St Luke's church, three skeletons (812, 1071 and 1086) showed evidence of this disorder. Osteomyelitis is frequently a complication of compound fractures, where the broken bone penetrates the skin allowing the invasion of bacteria into the marrow cavity. However, this was not the case with any named skeletons from St Luke's church. The isolated nature of the lesions precludes a systemic infection. Hence, it is most probable that the osteomyelitis formed from more superficial periostitis that progressively invaded the bone.

*Table 5.36 Prevalence of osteomyelitis in the named assemblage (n = 219)*

	Male	Female	Total
Adults	1.69% (2/118)	0.99% (1/101)	1.37% (3/219)
Subadults			0/22

#### Otitis media

The bones of the middle ear of skeleton 1218 showed evidence for chronic otitis media or middle ear infection. The malleus, incus and stapes of this young infant showed bony proliferation with spicules projecting from their surfaces. The lesions were still active at the time of death. These bony changes indicate prolonged infection, which would have caused considerable pain. Perforation of the tympanum or eardrum occurs in many untreated modern cases of otitis media, and hence, it is

*Table 5.37 Prevalence of otitis media in the named assemblage (n = 34)*

	Male	Female	Total
Adults	0	0	0
Subadults	0	8.33% (1/12)	4.54% (1/22)

likely that this individual also suffered hearing impairment. Although the cause of death of this infant could not be known for certain, it is very possible that this severe and prolonged ear infection may have spread internally, causing potentially fatal meningitis or encephalitis.

#### Chronic sinusitis

Chronic sinusitis was noted on four skeletons (522, 628, 916 and 977) of the named assemblage (1.66%). Due to the post-mortem fracturing of the maxillae, the maxillary sinuses of these individuals were exposed. It is highly probable that the true prevalence of the disorder was very much higher but could not be observed in skulls where the facial bones remained intact. The surfaces of the sinuses appeared roughened, rugose and porous due to overlying plaques of new bone. Chronic inflammation and/or infection of the maxillary sinuses frequently secondary to poor ventilation, allergy and the chronic exposure to polluted sooty air (Roberts and Manchester 1995, 131-132). This disease was particularly common in the smoggy cities of post-medieval Europe, and the prevalence increased in line with air pollution

*Table 5.38 Prevalence of maxillary sinusitis in the named assemblage (n =241)*

	Male	Female	Total
Adults	2.54% (3/118)	0.99% (1/101)	1.83% (4/219)
Subadults	0	0	0 % (0/32)

associated with industrialisation. Long-term exposure to air-borne pollutants was compounded by many industrial processes, leaving industrial and manufacturing workers (eg. miners, foundry and cloth workers) at severe risk of diseases of the ears, nose, throat and chest.

#### Chronic respiratory disease

Respiratory disease was commonplace in the medieval period and became even more of a cause for ill health following rapid urbanisation in the later post-medieval period. From the 18th century, industrialisation led to a vast influx of rural poor into the cities. Living conditions amongst the slums of the urban working classes were poor with overcrowding within poorly heated and poorly ventilated houses, malnutrition and poor general hygiene being the norm. Long hours worked in factories with air-

borne dust and chemicals also had a deleterious effect on respiratory health. One respiratory disease that thrived in these conditions was pulmonary tuberculosis, which became markedly more prevalent from the 17th century onwards, and by the 19th century reached epidemic proportions. Tuberculosis will be discussed more fully below.

The vast majority of respiratory disease leaves no trace on the bones. However, where a lesion (such as a bulla or abscess) approximates the ribs, resorption or new bone proliferation on the visceral surface of the rib may occur (Roberts et al 1998, 56). Traditionally, such lesions were associated with tuberculosis (TB) but Roberts et al (1998, 55-60) concluded that no differential diagnosis was possible without the presence of tuberculoid lesions in other parts of the skeleton. Acute lobar pneumonia, bronchiectasis (eg in chronic obstructive pulmonary disease, such as asthma, chronic bronchitis and emphysema), and less likely, metastatic carcinoma, non-specific osteomyelitis and syphilis may all be possible causes.

New bone growth was noted on the ribs of eight skeletons (3.32%) of the named assemblage of St Luke's church. In all cases, the lesions had healed before death, and hence, it is improbable that the respiratory disease that had caused these lesions was responsible for the demise of these individuals.

### Specific infections

#### Tuberculosis

Archaeological evidence of tuberculosis (TB) afflicting humans dates back at least to the Neolithic period, but in Europe it was from the 16th century that TB increased noticeably amongst urban populations, causing 20% of all recorded deaths at that time, the greatest concentration being in London (Johnston 2003, 339). This trend continued over the post-medieval period. By the early 19th century, autopsies undertaken on the most indigent dwellers of cities such as Paris and London revealed that close to 100% of all cadavers examined had developed tubercular lesions at some time in their lives, although many had died of other causes (ibid). Deaths from pulmonary tuberculosis or consumption (based on the Bills of Mortality of the 18th and 19th centuries) afflicted an estimated 400-500,000 people, making it the most common cause of death in this period (Roberts and Cox 2003, 338).

Like most infectious diseases, TB was principally but by no means exclusively, a disease of poverty and urbanisation. Spread by droplet infection, the

overcrowded and poorly ventilated housing and workplace conditions of these groups greatly facilitated its transmission amongst the urban poor. Greater vulnerability to the disease was noted in some occupation groups, with female textile factory workers exhibiting the highest TB rates of all occupational groups (Johnston 2003, 340).

TB is caused by the bacterium *Mycobacterium tuberculosis*, which most commonly invades lung tissue, but also may be found in the bones, the skin (where it was known as scrofula or the King's Evil), the gastrointestinal tract and the central nervous system (where it may cause tubercular meningitis). The bacteria may lay dormant in the body tissues for many years, but may become active when the host's immunity is compromised, as occurs when an individual is diseased or malnourished.

In approximately 90% of cases, tuberculosis leaves no trace on the skeleton, and hence, osteological prevalence of the disease drastically underrepresents the true pathology rates of this disease. Where bony lesions do occur, the most common locations are on the visceral surfaces of the ribs (but this may not be specific to tuberculosis), the vertebrae (in 25-50% of cases), and the hip and knee joints (Roberts and Manchester 1995, 141). New bone was present on the visceral surface of the ribs of eight skeletons of the named assemblage from St Luke's church (see above). However, in the absence of other characteristic lesions, a specific diagnosis of tuberculosis could not be made.

Two other skeletons (538 and 1142) displayed characteristic lytic and proliferative changes in the thoracic vertebrae. The former, Thomas Giles, a young adult, had characteristic smooth-walled lytic lesions in the bodies of T5-8 and L1. Frederick Welsted, another young adult male, displayed sub-circular lesions on the inferior and superior surfaces of the bodies of T11- L1, which were tentatively diagnosed as tubercular. The lesions had exposed the trabecular structure beneath. The average size of the lesions was 5-7 mm with a depth of 4-6 mm.

#### Congenital syphilis

Venereal syphilis was long the most serious and dreaded of the sexually transmitted diseases. The disease was first encountered in the western world in the 15th century AD, and rapidly spread across Europe (Roberts and Cox 2003, 340). By the post-medieval period, the 'great pox' or the 'French pox' (as syphilis was known in England) had become a significant health problem. Prevention of contagion using early forms of condoms, and treatments using mercury and guaiacum were largely

unsuccessful (ibid). It was really only with the invention of penicillin in the 1930s that any serious inroad was made into control of this disease. Venereal syphilis is a sexually transmitted infection caused by the bacterium, *Trepanima pallidum*, and is the only one of the treponematoses (a group of diseases that includes yaws, pinta and endemic syphilis) that may have a fatal outcome. Syphilis is transmitted by sexual contact or may be passed from an infected mother to her foetus. The latter is known as congenital syphilis.

Venereal syphilis acquired in adulthood is a chronic infection characterised by three clinical stages separated by latent stages with no visible symptoms (Arrizabalaga 2003, 316). In primary syphilis, a small painless ulcer or chancre appears on the genitals (and less commonly elsewhere) within 2-6 weeks of infection. In most cases, after a brief latent period, there is a secondary stage characterised by widespread lesions on the skin and in the internal organs, a painless rash, fever, malaise and bone ache. These symptoms disappear after a few weeks, but in 25% of sufferers they recur during the first two years (ibid). The tertiary stage only develops in a third of untreated cases, and only following a latent phase that may vary in length from 1 to more than 20 years. It is this tertiary stage that causes such profound systemic damage that results in insanity and death. The bacterium causes progressive destruction of a number of systems of the body, including the skin, mucous membranes, bones, the heart and blood vessels and the nervous system. Nervous system involvement causes a loss of positional sense and sensation that manifests as locomotor ataxia (a stumbling, high stepping gait), and bouts of insanity, generally known as general paralysis of the insane (ibid; Roberts and Manchester 1995, 153). Fatality from tertiary syphilis occurs through cardiovascular involvement, such as ruptured aneurysm, or cardiac valve failure.

Congenital syphilis refers to syphilis transmitted to the unborn child of a mother suffering from venereal syphilis, and occurs in 80% of pregnancies where the mother is infected (Aufdeheide and Rodriguez-Martin 1998, 164). The spirochete bacteria are transmitted across the placenta to the foetus after the first 16-18 weeks in utero. Spontaneous abortion and stillbirth are commonly associated with the condition. Surviving infants frequently manifest with developmental anomalies, such as deafness, cusp malformations of the permanent dentition (Hutchinson's incisors and mulberry molars), interstitial keratitis, impaired cognitive development,

periostitis, osteochondritis and osteomyelitis. Syphilitic infection of the scalp, historically described as 'scald head', was a very visual, unsightly manifestation of congenital syphilis.

Four individuals in the named assemblage from St Luke's Church (skeletons 363, 975, 1072 and 1258) showed dental malformations characteristic of congenital syphilis. No skeletal manifestations of syphilis were noted in these skeletons. One neonate (skeleton 997) with gross dental enamel hypoplasia may have also suffered from this condition, but a differential diagnosis could not be made confidently in this case.

The London Bills of Mortality attributed between one and 30 deaths per year to 'scald head' in the period between 1740-1810 (Roberts and Cox 2003, 341-2). The true mortality rate of congenital syphilis was probably much higher. Nevertheless, many sufferers of congenital syphilis did survive into mature adulthood, as evidenced by the young adult William Clarke (skeleton 1258) and a prime adult male of unknown name (skeleton 975). James MacCallum (skeleton 1072) was less fortunate, dying within the first year of life. Keith Stewart (skeleton 363) survived into adolescence and may well have died of an unrelated disorder.

#### *Other pathologies*

##### Paget's disease

Male skeleton 898 aged 36 from the departum plate inscription and osteologically aged between 45-55 years may have had Paget's disease. It is a condition of unknown aetiology characterised by a profound increase in both bone resorption and new bone formation resulting in simultaneous mixtures of lytic and sclerotic processes, initiating as a localised condition but often terminating as a widespread state. The clinical, symptomatic form of the disease is certainly one of older people, most commonly aged over 60 years (Aufderheide and Rodríguez-Martin 1998, 413). There was thickening of the skull; particularly at the supra-orbital margins, thickening and porosity with new bone formation of the sternum and the manubrium, bodies of all the vertebrae. The clavicles, shafts of the humeri, ulnae, radii, femora, tibiae and fibulae are all markedly thickened and porous with areas of plaque formation and spicules. The porosity is caused by hypervascularization while the thickening, caused by abnormal osteoblastic activity is most prominent in the femora and tibiae to the extent where the cortices appear sclerotic. All the bones are heavier than normal. The

involvement of multiple bones and the thickening of the shafts due to the proliferation of new bone are consistent with Paget's disease.

### Congenital anomalies

A number of congenital anomalies are present in many individuals but which would have little or no effect on their physical wellbeing. They occur as the result of minor genetic mutations and as such may be inherited. Many are thought to indicate familial relationships between members within an assemblage. Sacralization (fusion of the last lumbar vertebra to the first sacral segment) was present in four individuals (1.83 %). Another midline defect, Spina bifida occulta, was recorded in three adults (skeletons 117, 121 and 364) of the named assemblage (1.37%). This condition involves non-fusion of some or all of the neural arches of sacral segments dorsally. As a result, the lower portion of the spinal canal is not fully enclosed by bony tissue. Unlike spina bifida proper, there is no clinical sequelae to this condition, and at most the abnormality may be marked superficially by a small tuft of hair on the lower back.

### *Medical interventions*

#### Post-mortem dissection

In the Georgian and Victorian periods, post-mortem dissection was an uncommon procedure, and usually one over which the deceased and their relatives exercised little control. In the 18th century there was a growing need in medical institutions to be provided with cadavers on which students might learn anatomy and practice dissection. In 1752, the Company of Surgeons was granted the corpses of all executed felons. However, demand far outstripped supply, and many additional cadavers were supplied to anatomy halls by 'resurrectionists', who raided graveyards, exhuming corpses and selling them on for a handsome profit (Porter 1997, 318). Public outrage at this practice reached a height in 1829 with the notorious case of Burke and Hare. The outcome of this outrage was the passing of the Anatomy Act (1832), in which the medical profession could take for dissection all 'unclaimed bodies' of those dying without family, or those dying in the workhouse or hospitals. As a result of the act, there was a reduction in body-snatching, but the act also served to deepen the fear and disgrace of dying 'on the parish'.

The antithesis to the notion of being dissected was based around religious and social perceptions. The Christian belief in the resurrection of the whole body on Judgement Day led to fears that dissection would damage the spiritual state of the

dissected person. A deep-seated solicitude for the corpse causes reactions of revulsion at the indignity that the body suffered during exhumation and dissection. Particularly with regards to female corpses, the physical exposure of the naked body to the gaze of young men was perceived as harrowing, a process tantamount to sexual assault (Rugg 1999, 225).

*Table 5.40 The prevalence of craniotomies in the named assemblage (n = 241)*

	Male	Female	Total
Adults	2.54% (3/118)	0	1.36% (3/219)
Subadults	0	8.33% (1/12)	4.54% (1/22)

In view of these almost universal sentiments regarding dissection at this time, it is puzzling that these four skeletons at St Luke's church had undergone autopsy. All four skeletons had been buried within the crypt in lead-lined coffins, and hence, they were highly unlikely to have been executed felons. Nor would they have died on the parish in a friendless, impecunious state. It is possible that the adults and the parents of skeleton 360 (the 5 year old Emma Gardiner) had consented to the procedure, possibly because they held unusually progressive views on medicine and the academic necessity for dissection. A less probable alternative explanation is that these craniotomies were performed on the sly without the consent of the deceased or their relatives. Such craniotomies are fairly easy to hide from the incurious if the dissection of the skin is concealed beneath the hair. It is possible that their families may have interred them remaining none the wiser of these interventions.

*Table 5.41 Burial location of the skeletons that had undergone autopsy (n = 4)*

Skeleton number	Burial location	Date of death	Name	Age at death
360	Crypt	1825	Emma Gardiner	5 years, 11 months
469	Crypt	1842	Thomas Tribe	53 years
923	Crypt	1823	Thomas Roberts	20 years
986	Crypt	1850	George Walford	51 years

Medical curiosity may have prompted the dissection of Thomas Tribe (skeleton 469). He had suffered a facially disfiguring cancer (possibly an osteolytic metastatic carcinoma), which had left a large lytic lesion in his left eye orbit, and had caused considerable bony destruction of the orbit and nasal cavity (Plate 5.2). George Walford (skeleton 986) had active rib lesions at death, suggesting chronic respiratory infection (possibly TB). His corpse had undergone a craniotomy and also a sternotomy (an inverted y-shaped incision through the sternum). Sternotomies are performed when the soft tissue of the thorax (lungs and heart) is to be investigated. It is possible that the medical practitioners who undertook this autopsy were particularly interested in the nature of George Walford's respiratory disease.

*Table 5.42 Summary of autopsy prevalence six post-medieval burial populations in England*

Site	Percentage of population
St.Luke's, Islington (named)	1.66% (4/241)
St.Luke's, Islington (unnamed)	0.31% (2/655)
St Bartholomew's, Penn	0.81% (3/372)
Cross Bones, Southwark, London	0.67% (1/148)
Newcastle Infirmary, Newcastle	1.59% (3/189)
St Bride's lower churchyard, Fleet Street, London	3.38% (18/533)

## Conclusion

The burial location within the church crypt, extramural vaults and brick-lined shaft graves of the majority of the named skeletons of St Luke's church strongly suggests that this population was composed principally of the middle classes resident in Islington. Where osteological comparisons could be made between the named and unnamed burial assemblages, differences did exist between the populations. However, these were not as extreme as postulated. For example, there was no difference in either male or female stature between these groups (usually a fairly sensitive indicator

of stress in the growing years). However, the general age distribution within the adult populations did differ, with a far smaller proportion of the unnamed reaching old age (16.56% compared to 61.83% in the named group's 50+ age bracket). Although a higher proportion of named individuals did die in young adulthood (9.12% versus 5.52% of the unnamed group), it was apparent that far more unnamed individuals died in the prime to mature age brackets, indicating overall a shorter general lifespan within this population. However, the unnamed assemblage of St Luke's church do not appear as deprived as the destitute working classes of other parts of London, such as those interred in the Cross Bones burial ground, Southwark.

Islington of the late Georgian/early Victorian period was a gracious suburb, described by Goldsmith (in Porter 2000, 148) as 'pretty neat town, mostly built of brick, with a church and bells', celebrated for its well or spa of health-giving waters, its fine air and its high location with a magnificent panorama of the city. It was a far cry from the tangle of warehouses and slums of Southwark, and had more in common with the new modern urban developments of the West End, such as Bloomsbury. The working classes of Islington appeared to have benefited from the cleaner air and removed location from the factories and slums of the East End. Although certainly not living off the fat of the land, overall the working classes in Islington do appeared to have enjoyed a better quality of life than experienced elsewhere in the metropolis.

The named assemblage of St Luke's church have much more in common with the crypt burials of Christ Church, Spitalfields, St George's church, Bloomsbury, and St Nicholas' church, Sevenoaks. They appear to reflect the middle classes of this genteel suburb, who did experienced some deleterious effects on health that accompany affluence and excess, but which more importantly shielded them from the most damaging effects of living in the mushrooming, overcrowded, polluted, industrial metropolis that was London of the eighteenth and nineteenth centuries.

Table 5.43 Summary of the skeletal pathology noted in the named assemblage (n = 241)

Coffin Number	Osteological Age	Osteological Sex	Forename	Surname	Pathology	Comments
<b>Congenital disorders</b>						
970	young adult	female	Matilda	Gibson	congenital dislocation of the hip	Bilateral. Resulted in ankylosis of right hip joint. Left still mobile
<b>congenital dislocation of the hip</b>						
888	mature adult	male	Charles		club foot	Right foot: all tarsals fused, malalignment superior-inferior row rather than mediolateral, causing anterior part of foot to be inverted.
<b>Club foot</b>						
619	aging adult	male	Charles	Cole	developmental defect	Bipartite maxillary sinous cavity, right side
1078	prime adult	male	Thomas	Roberts	developmental defect	Left and right 1st metatarsal, proximal joint surface. Left and right proximal phalanx for the metatarsals.
1131	aging adult	female	Ester	Taylor	developmental defect	Open neural canal on C1
777	prime adult	male	John	Russell	developmental defect	T2, underdeveloped transverse process. Abnormal inferior articular facet, split and 2 articular surfaces.
<b>developmental defect</b>						
355	mature adult	male	Charles	Cuerton	os acromiale	Left scapula
1203	ageing adult	male	William	Farmer	os acromiale	Left and right scapulae
<b>os acromiale</b>						
723	adult	female	Elizth (Elizabeth)	Treson	scoliosis	Likely to have been congenital in origin; T3-9 affected
860	ageing adult	female	Mary	Lockin	scoliosis	Spinal scoliosis, spine deviates to the right in L2 region. Second curvature occurs in T12 to the left. T3-4, L1-2, L3-4 are ankylosed. Ribs have been modified on the right side due to compression on the ribs. The aetiology is unknown.
<b>scoliosis</b>						
<b>Trauma</b>						
114	prime adult	male	John	Bailey	compression fracture	T11, Degenerative.

0420

343	mature adult	male	Charles	Stokes	compression fracture	L4. Differential diagnosis. New bone formation on the ribs + collaps of L4 (tuberculosis?)
<b>compression fracture</b>	<b>2</b>					
117	aging adult	male	Samuel	Roberts	depressed fracture	Circular lesion to cranium
538	young adult	male	Thos (Thomas)	Giles	depressed fracture	Frontal bone
920	aging adult	female	Sarah	Fuller	depressed fracture	Left parietal, healed.
967	mature adult	male	John	Farmer	depressed fracture	Frontal bone
<b>depressed fracture</b>	<b>4</b>					
281	aging adult	male	Noah	Nicholls	fracture	Left rib
355	mature adult	male	Charles	Cuerton	fracture	Nasal fracture. exostoses also present on the alveolar margin of left maxilla. Related trauma?
364	prime adult	female	Sarah	Hathorn	fracture	Right 3rd metacarpal
393	aging adult	male	John	Sheppard	fracture	Right 10th and 11th and left 10th rib
469	aging adult	male	Thomas	Tribe	fracture	Right 2nd metacarpal
479	aging adult	female	Mary	Hooker	fracture	Colliers fracture, right radius
513	aging adult	male	Thos (Thomas)	Dennis	fracture	Rib and right fibula (upper 1/3 midshaft) both healed
538	young adult	male	Thos (Thomas)	Giles	fracture	?? Right ulna, inferior to the coronoid process, posterior side. OR periostitis, lesion active.
614	mature adult	female	Elizabeth	Egner	fracture	2 ribs, unsided
616	aging adult	male	George	Girsewood	fracture	1 unsided rib
697	aging adult	female	Elizth (Elizabeth)	Sewell	fracture	1 right rib, middle of rib cage.
707	mature adult	male	Andrew	Egner	fracture	Right foot, distal phalanx
788	mature adult	male	George	Wright	fracture	Left clavicle, longstanding and healed
845	aging adult	male	John	Wright	fracture	2 right ribs, transverse and oblique fractures
856	aging adult	female	Margaret	Lovell	fracture	2 right ribs
908	mature adult	female?	Ann	Lucas	fracture	Proximal phalanx of the feet.
910	aging adult	male	William	Rone	fracture	Left rib situated towards the middle of the rib cage. Healed.
936	aging adult	male	James	Allan	fracture	Distal end of shaft of left humerus.
961	mature adult	male	Edward	Keat	fracture	1 left rib, healed and longstanding.
967	mature adult	male	John	Farmer	fracture	Left rib number 11

1009	aging adult	female?	Mary	Clark	fracture	1 right rib, mid chest region. Healed
1145	mature adult	female?	Mary	Lan	fracture	Left tibia, articular surface
1147	prime adult	male	Michael	Lan	fracture	1 left rib
1203	aging adult	male	William	Farmer	fracture	2 right ribs, partly healed
fracture		24				
162	adult	female?	Thomas	Brown	oblique fracture	Left fibula, distal end of shaft
522	aging adult	male	Laurance	Sidney	oblique fracture	Distal end of the shaft of left tibia. Caused by trauma from behind.
845	aging adult	male	John	Wright	oblique fracture	Proximal fibula
859	young adult	male	James	Lumley	oblique fracture	Distal third of left humeral shaft.
1065	prime adult	male	William	Bukridge	oblique fracture	Proximal end of right femoral shaft.
1145	mature adult	female?	Mary	Lan	oblique fracture	Left distal fibula
1177	aging adult	female	Celia	Boyle	oblique fracture	Distal left radius, Collies fracture. Healed
1208	aging adult	male	Sarah	Willecox	oblique fracture	Left tibia, distal shaft. Left fibula, proximal shaft. Healed.
oblique fracture		8				
468	prime adult	female	Susannah	Joselyn	soft tissue trauma	Enthesopathy at proximal right fibula. Insertion point for <i>biceps femoris</i> . Muscle tear at the ligament insertion point.
619	aging adult	male	Charles	Cole	soft tissue trauma	Right distal femur, insertion of <i>adductor magnus</i> , large enthesophyte.
705	aging adult	male	Thomas	Willet	soft tissue trauma	Left femur, linea aspera. Enthesopathy present at the insertion point for <i>Adductor brevis</i> or <i>magnus</i> . Healed.
845	aging adult	male	John	Wright	soft tissue trauma	Enthesophyte formation associated with the fracture at insertion point for <i>Vastus intermedius</i>
862	adult	female?	Elizth (Elizabeth)	Baillie	soft tissue trauma	Enthesophyte present left distal humerus shaft. Attachment for the brachio-radius muscle.
1078	prime adult	male	Thomas	Roberts	soft tissue trauma	Enthesopathy on left fibula, proximal end.
soft tissue trauma		6				
1170	prime adult	female	Mary	Porter	transverse fracture	2 proximal phalanges of foot. Healed.
transverse fracture		1				
701	aging adult	male	Thos (Thomas)	Moor	osteochondritis dissecans	Left femur, lateral condyle
1078	prime adult	male	Thomas	Roberts	osteochondritis dissecans	Right humerus, distal end

1223	prime adult	male	Rouland	Wilkes	osteocondritis dissecans	Right and left distal articular surfaces of the tibiae.
<b>osteocondritis dissecans</b> 3						
890	aging adult	male	Samuel Austin	Fuller	subluxation	Inferior dislocation of left humerus. Longstanding, new socket has been formed.
<b>subluxation</b> 1						
<b>Neoplasm</b>						
122	aging adult	female	Ann	Webb	button osteoma	Left side on frontal bone
772	mature adult	male	John	Amburger	button osteoma	Left frontal
777	prime adult	male	John	Russell	button osteoma	Right parietal
846	aging adult	female	Elizabeth	Lorimer	button osteoma	Right side, occipital bone
1145	mature adult	female?	Mary	Lan	button osteoma	Right parietal and frontal bone (x 2)
<b>button osteoma</b> 5						
469	aging adult	male	Thomas	Tribe	malign neoplasms	Possibly osteolytic metastatic carcinoma. Large lytic lesion present in left orbit. Considerable destruction of the orbit and nasal cavity
973	mature adult	female	Mary	Robinson	malign neoplasms	Multiple myeloma or osteolytic metastatic carcinoma. The latter being more probable.
<b>malign neoplasms</b> 2						
<b>Metabolic disorders</b>						
967	mature adult	male	John	Farmer	acromegaly	
<b>acromegaly</b> 1						
360	infant 2	subadult	Emma	Gardner	cribia orbitalia	Grade 3, right and left orbits
361	aging adult	male	Thomas	Sowter	cribia orbitalia	Grade 1, healed
363	juvenile	unknown	Keith	Stewart	cribia orbitalia	Grade 1, bilateral
467	young adult	male	John	Pugh	cribia orbitalia	Bilateral
468	prime adult	female	Susannah	Joselyn	cribia orbitalia	Grade 3, active lesions
537	mature adult	female	Susannah	Smith	cribia orbitalia	Bilateral, Grade 3, active
538	young adult	male	Thos (Thomas)	Giles	cribia orbitalia	Grade 3, bilateral, active
540	infant 1	subadult	Elizabeth	Giles	cribia orbitalia	Bilateral, grade 2
602	infant 2	subadult	Louisa	Goxall	cribia orbitalia	Grade 3, active
609	mature adult	female	Susanna	Rogers	cribia orbitalia	Grade 1, bilateral
618	aging adult	female	Ann	Seward	cribia orbitalia	Grade 3, active lesions

724	mature adult	female	Ann	Hooker	cribia orbitalia	Grade 3, healed.
782	mature adult	female	Catherine	Bailey	cribia orbitalia	Grade 2, healed.
922	prime adult	female	Sarah	Palmer	cribia orbitalia	Bilateral, Grade 1
966	aging adult	male	Andrew	MacKenzie	cribia orbitalia	Left orbit, grade 2. Lesion healed
967	mature adult	male	John	Farmer	cribia orbitalia	Bilateral, Grade 2, active.
970	young adult	female	Matilda	Gibson	cribia orbitalia	Grade 1, healed.
973	mature adult	female	Mary	Robinson	cribia orbitalia	Grade 1, healed
977	prime adult	male	George	Nightingale	cribia orbitalia	Bilateral, Grade 2, active.
985	aging adult	female	Ann	Bateman	cribia orbitalia	Grade 1, healed
986	aging adult	male	George	Walford	cribia orbitalia	Left grade 4, right grade 1, both active
1086	mature adult	male	Thomas	Fisher	cribia orbitalia	Bilateral, active
1142	young adult	male	Charles Frederick	Wellsted	cribia orbitalia	Grade 3, active, bilateral
<b>Cribr orbitalia</b> 23						
538	young adult	male	Thos (Thomas)	Giles	porotic hyperostosis	Parietals, active
628	mature adult	male	Thomas	Moore	porotic hyperostosis	Parietals and occipital, healed.
708	aging adult	male	John	Horton	porotic hyperostosis	Parietals and frontal bone, healed
709	young adult	male	John	Horlor	porotic hyperostosis	Parietals
905	prime adult	male	Fred	Gibson	porotic hyperostosis	Parietals, healed.
973	mature adult	female	Mary	Robinson	porotic hyperostosis	Parietals and frontal, healed
977	prime adult	male	George	Nightingale	porotic hyperostosis	Parietals, active
991	neonate	subadult	James Charles Fredk (Fredrick)	Lumley	porotic hyperostosis	
1142	young adult	male	(Fredrick)	Wellsted	porotic hyperostosis	Parietals, healed
1223	prime adult	male	Rouland	Wilkes	porotic hyperostosis	Parietals and frontal bones, healed.
<b>porotic hyperostosis</b> 10						
1157	aging adult	male	Peter	Clarke	osteoporosis	Very light bones. T12 and L5, collapse of the vertebral bodies, no healing evident. Trabecular structure very much reduced.
<b>osteoporosis</b> 1						
475	mature adult	female	Elizabeth	Ainge	rickets	Anterior bowing of the femora, healed.

538	young adult	male	Thos (Thomas)	Giles	rickets	Lateral bowing of the tibiae. Healed
539	aging adult	male	James	Jones	rickets	Anterior bowing of both femora
704	aging adult	female	Elizabeth	Willet	rickets	Anterior bowing of the femora, healed.
778	mature adult	female?	Elizth (Elizabeth)	Seward	rickets	Anterior bowing of both femoral shafts, healed.
779	aging adult	male?	Joseph	Seward	rickets	Anterior bowing of femora, lateral bowing of tibiae, healed.
862	adult	female?	Elizth (Elizabeth)	Baillie	rickets	Bowing of the femora and tibiae, healed.
922	prime adult	female	Sarah	Palmer	rickets	Lateral bowing of the tibiae and fibulae. Healed.
927	neonate	subadult	Isabella	Fuller	rickets	Active
935	prime adult	female	Elizth (Elizabeth)	Richardson	rickets	Bilateral anterior bowing of the femora. Healed.
975	prime adult	male			rickets	Slight lateral bowing of tibiae and humeri.
990	aging adult	female	Elizabeth	Hewlett	rickets	Lateral bowing of the tibiae, healed.
1086	mature adult	male	Thomas	Fisher	rickets	Anterior bowing of the femoral shafts. Healed.
1203	aging adult	male	William	Farmer	rickets	Anterior bowing of right and left femoral shafts. Lateral bowing of both tibiae. Healed.
1215	infant 1	subadult	Alfred	Matthews	rickets	Anterior bowing of the femoral shafts.
1218	neonate	subadult	Sarah	Hyde Clarke	rickets	Active infantile rickets
1261	neonate	subadult	Alfred	Clarke	rickets	Infantile rickets, active.
<b>rickets</b> 17						
<b>Joint disease</b>						
114	prime adult	male	John	Bailey	ankylosing spondylitis	Fusion of R side of sacrum to auricular surface and osteophytic projections from L auricular surface. Fusion of L1-2, T10 to T5 (1/2 kyphosis) and T4 and T3. Osteophytic projections at other muscle insertion points suggest DISH but spinal fusion more typically AS.
1208	aging adult	male	Sarah	Willcox	ankylosing spondylitis	
<b>ankylosing spondylitis</b> 2						
254	aging adult	female	Cath	Wood	DISH	Osteophyte formation on ligament and muscle insertion points. Spine fused, "candle wax" appearance, T2-T11.
616	aging adult	male	George	Girsecwood	DISH	Enthesophytes and candle wax appearance of osteophytes on spine. T4-5, T6-8, T9-10 fused
778	mature adult	female?	Elizth (Elizabeth)	Seward	DISH	Fusion of spinal elements C2-3, T5-10 and T11-12.
920	aging adult	female	Sarah	Fuller	DISH	Fused vertebral segments and enthesophytes.
951	aging adult	male	John	Stubbs	DISH	Post-mortem damage extensive, obscures secure diagnosis

<b>DISH</b>	<b>5</b>					
616	aging adult	male	George	Girsecwood	rheumatoid arthritis	6 proximal phalanges of the hands with eburnation - possible lytic lesions. Possibly just osteoarthritis
860	aging adult	female	Mary	Lockin	rheumatoid arthritis	Proximal interphalangeal joint, digit 3, right hand and left hand. Erosive lesions present.
<b>rheumatoid arthritis</b>	<b>2</b>					
364	prime adult	female	Sarah	Hathorn	ankylosis	C4 and 5 ankylosed. Anterior displacement of C4, possibly trauma
537	mature adult	female	Susannah	Smith	ankylosis	Left femoral head, partial superior dislocation resulting in ankylosis
619	aging adult	male	Charles	Cole	ankylosis	Right sacroiliac joint. Degenerative
629	aging adult	male	Thos (Thomas)	Coventry	ankylosis	Left sacro-iliac joint (possibly degenerative)
775	adult	male?	William	Feast	ankylosis	Sacro-iliac joint. (possibly degenerative)
921	adult	unknown	Thomas	Young	ankylosis	Sacro-iliac joint, possibly degenerative
1062	aging adult	male	Richard	Sumption	ankylosis	Distal interproximal joint of a hand digit
1176	adult	male?	Thomas	Boyle	ankylosis	Post-traumatic fusion of a proximal and intermediate phalanx of the foot.
<b>ankylosis</b>	<b>8</b>					
113	aging adult	female	Mary	Bailey	degenerative joint disease	Right distal femur and patella, Right and left acromial facets
162	adult	female?	Thomas	Brown	degenerative joint disease	Left fibula, distal joint surface. Left tibia, distal joint surface
194	adult	male	James	Eltham	degenerative joint disease	Left and right distal femora. Left and right 1st metatarsals
262	aging adult	female	Sarah	Hathorn	degenerative joint disease	Acromial ends of the clavicles
303	aging adult	female	Recca (prob. Rebecca)	Sowter	degenerative joint disease	Left 1st metacarpal, proximal joint surface
343	mature adult	male	Charles	Stokes	degenerative joint disease	Left and right distal femora and patellae. Right acetabulum
361	aging adult	male	Thomas	Sowter	degenerative joint disease	Right and left clavicles, both ends. Right and left femora, distal ends. Right and left tibiae, proximal ends.
362	mature adult	unknown	Ann	Brown	degenerative joint disease	Left patella
469	aging adult	male	Thomas	Tribe	degenerative joint disease	Osteophytes present at 1st metatarsals, both patella, right clavicle and scapula (glenoid fossa), right and left proximal fibulae, right and left acetabulae, right and left iliac crests
475	mature adult	female	Elizabeth	Ainge	degenerative joint disease	Right femur, osteophyte formation on the margins of the condyles
478	aging adult	female	Mary	Tilford	degenerative joint disease	Acromio-clavicular joints, bilateral. Left acetabulum
513	aging adult	male	Thos (Thomas)	Dennis	degenerative joint disease	Right calcaneus, talus, navicular and distal 1st metatarsal. Left distal metatarsal

537	mature adult	female	Susannah	Smith	degenerative joint disease	Right femoral condyles and patellar surface
539	aging adult	male	James	Jones	degenerative joint disease	Both acetabulae, right talus and cuboid, left cuboid, 2nd and 3rd cuneiforms
542	mature adult	male?	?	Nash	degenerative joint disease	Acetabulae (L+R), Condyles of left femur, articular surface of left tibia
600	mature adult	female	Catherine	Lowe	degenerative joint disease	Proximal articular surface of left tibia
603	aging adult	female	Mary	Deer	degenerative joint disease	Right and left glenoid fossae, scapulae. Right and left acromio-clavicular joints, sternal end of both clavicles
616	aging adult	male	George	Girsewood	degenerative joint disease	6 proximal hand phalanges (RA?), Right and left capitates, Right lunate, right and left trapezia, left triquetral. 2 proximal foot phalanges, left and right 1st metatarsals (heads), left metacarpals 1-4. Right and left clavicles (both ends)
617	aging adult	female	Lydia	Prosser	degenerative joint disease	Right and left acromio-clavicular joints, Right and left acetabulae, Right and left distal femora.
618	aging adult	female	Ann	Seward	degenerative joint disease	Right and left distal femora, right and left proximal tibiae
619	aging adult	male	Charles	Cole	degenerative joint disease	Right prox humerus, right acetabulum and femoral head.
620	aging adult	female	Sophia	Cole	degenerative joint disease	Left glenoid fossa, manubrium. Right and left distal femora, patellae and proximal tibiae. Right and left clavicles, both ends. Right acetabulum and femoral head. Right and left hand; 1st metacarpal and proximal and distal phalanx. Right capitate
626	aging adult	female	Sophia	Louch	degenerative joint disease	Right acromio-clavicular joint. Right and left distal femora. Left 1st metatarsal, distal end.
655	mature adult	male	Ann	Davidson	degenerative joint disease	Right and left distal femora
656	aging adult	female	Mary	Williamson	degenerative joint disease	Sacro-iliac joint, right and left. Right and left femora, distal ends.
657	aging adult	male	Cuthbert	Wilkinson	degenerative joint disease	left and right acromio-clavicular joints. Left distal femur and patella
697	aging adult	female	Elizth (Elizabeth)	Sewell	degenerative joint disease	Left and right head of femora. Right and left sterno-clavicular joint. Manubrium. Left distal radius.
699	aging adult	male	Thomas	Willet	degenerative joint disease	Right and left patellae
701	aging adult	male	Thos (Thomas)	Moor	degenerative joint disease	Left and right distal femora and proximal tibiae.
704	aging adult	female	Elizabeth	Willet	degenerative joint disease	Right patella.
705	aging adult	male	Thomas	Willet	degenerative joint disease	Right hand, 3 intermediate phalanges (distal end). Left hand 1 intermediate phalanx, digit 3.

708	aging adult	male	John	Horton	degenerative joint disease	Right and left acromio-clavicular joints. Right and left humeral heads. Right and left proximal ulnae. Right and left 1st-3rd and 5th metacarpals. Proximal phalanges of digit 2, 3 and 5, both hands. Distal interphalangeal joint of digit 2 and 3. Rig
719	mature adult	female?	Elizabeth	Jones	degenerative joint disease	Left calcaneus, talus
724	mature adult	female	Ann	Hooker	degenerative joint disease	Left glenoid fossa. Right and left acetabulae. Left and right distal femora and both patellae
764	aging adult	male	John	Gardner	degenerative joint disease	Right calcaneus, talus and medial cuneiform, 1st metatarsal and proximal phalanx. Left calcaneus and talus, fusion of medial and intermediate cuneiforms. Medial end of clavicles. Both glenoid fossae. Right and left distal ends of both femora.
779	aging adult	male?	Joseph	Seward	degenerative joint disease	Left acromio-clavicular joint
788	mature adult	male	George	Wright	degenerative joint disease	Right humeral head
831	aging adult	female	Mary	Monk	degenerative joint disease	Right and left glenoid fossae, right and left patellae, left and right 1st metatarsals, distal end. Left ulna, proximal. Sacro-iliac joints. Right and left calcanei
846	aging adult	female	Elizabeth	Lorimer	degenerative joint disease	Medial end of right and left clavicles. Manubrium. Right and left acetabulae. Right and left radii, distal ends.
851	mature adult	female	Elizth (Elizabeth)	Maxwell	degenerative joint disease	Right and left patellae
855	aging adult	male	Trefusis	Lovell	degenerative joint disease	Left and right acromio-clavicular joints. Right and left distal femora and both patellae
858	aging adult	male	Thoms (Thomas)	Dallison	degenerative joint disease	Right and left acetabulae, right and left glenoid fossae. Left and right acromio-clavicular joint.
859	young adult	male	James	Lumley	degenerative joint disease	Right 1st metatarsal, distal end.
861	aging adult	male?	Alex	Bailly	degenerative joint disease	
862	adult	female?	Elizth (Elizabeth)	Baillie	degenerative joint disease	Right femoral head. Right and left distal femora. Right and left patellae. Right and left proximal tibiae.
888	mature adult	male	Charles		degenerative joint disease	Right 1st-3rd metatarsals. Left calcaneus, anterior facet.
890	aging adult	male	Samuel Austin	Fuller	degenerative joint disease	Left sterno-clavicular joint. Right glenoid fossa
895	aging adult	female	Hannah	Hickin	degenerative joint disease	Left trapezium. Left and right digit 1, metacarpo-phalangeal joints. Right scaphoid. Right and left acetabulae
925	mature adult	female	Christina	Lanton	degenerative joint disease	Both patellae
935	prime adult	female	Elizth (Elizabeth)	Richardson	degenerative joint disease	Right and left calcanei. Left and right 1st metatarsals, heads. Left and right femora, distal end.
936	aging adult	male	James	Allan	degenerative joint disease	Left glenoid fossa. Head of right radius.
946	mature adult	female	Lydia	Batty	degenerative joint disease	Right and left humeral heads. Right and left distal femora. Left patella and articular surface of left tibia.

961	mature adult	male	Edward	Kcat	degenerative joint disease	Left and right distal femora, both patellae and tibiae, proximal end. Right and left naviculars cuboids, calcanei and talus. All cuneiforms, both feet, proximal articular surfaces of metatarsal 1-5, both feet.
966	aging adult	male	Andrew	MacKenzie	degenerative joint disease	Left acromio-clavicular joint. Left and right acetabulae and femoral heads. Left 1st metacarpal, head. Left and right 1-3 metatarsals.
967	mature adult	male	John	Farmer	degenerative joint disease	Right and left femoral heads. Right and left distal femora.
968	aging adult	male?	Jane	Colchett	degenerative joint disease	Left acromio-clavicular joint
973	mature adult	female	Mary	Robinson	degenerative joint disease	Right and left distal femora
976	aging adult	male	George	Nightingale	degenerative joint disease	Right 1-5 metacarpals, left 1st metacarpal. 7 proximal, 4 middle and 3 distal hand phalanges. Right 1-5 and left 2-5 metatarsals. 9 proximal, 4 middle and 2 distal foot phalanges. Proximal right fibula. Right and left patellae.
980	mature adult	male	George	Lowe	degenerative joint disease	Right proximal phalanx, digit 1 of the foot
981	mature adult	male	Foy	Walford	degenerative joint disease	Left and right glenoid fossae. Right and left metatarsals, heads.
985	aging adult	female	Ann	Bateman	degenerative joint disease	Both glenoid fossae. Right acetabulum. Left and right distal femora, patellae and proximal tibiae
1008	aging adult	male	George	Scott	degenerative joint disease	Left sterno-clavicular joint.
1009	aging adult	female?	Mary	Clark	degenerative joint disease	Left and right acromio-clavicular joints. Left and right glenoid fossae. Left acetabulum. Right and left distal femora and patellae.
1068	mature adult	female	Elizabeth	Simpson	degenerative joint disease	Right auricular surface
1069	prime adult	male	Ann	Nightingale	degenerative joint disease	Right and left patellae. Right calcaneus, navicular and head of 1st metatarsal.
1071	aging adult	male?	Andrew	Duff	degenerative joint disease	Right and left glenoid fossae. Head of both humeri. Right proximal ulna. Distal left humerus, proximal left ulna.
1078	prime adult	male	Thomas	Roberts	degenerative joint disease	Right and left proximal ulnae. Left 1st metatarsal and proximal phalanx
1128	aging adult	male	William	Moore	degenerative joint disease	Right glenoid fossa. Left and right calcaneus. Left and right head of 1st metatarsal
1141	aging adult	male	William	Patch	degenerative joint disease	S1
1144	mature adult	female?	Mary	Millward	degenerative joint disease	Left glenoid fossa
1145	mature adult	female?	Mary	Lan	degenerative joint disease	Right and left humeral heads and glenoid fossae. Right proximal and distal interphalangeal joints of digit 2-4 (hand). Left distal interphalangeal joint of digit 2 (hand). Left distal femur, patella and proximal tibia. Left talus. Left distal fibula
1147	prime adult	male	Michael	Lan	degenerative joint disease	Left glenoid fossa

1153	prime adult	male	William	Moir	degenerative joint disease	Right patella
1155	mature adult	male	John	Smith	degenerative joint disease	Right and left sterno-clavicular joints and acromio-clavicular joints. Right and left distal femora and patellae. Left glenoid fossa. Left 2nd metatarsal, proximal end. Right and left distal phalanges of digit 1, feet.
1156	mature adult	female	Elizabeth	Farmer	degenerative joint disease	Left and right acetabulae. Left and right distal humeri. Left acromio-clavicular joint. Right sterno-clavicular joint. Left and right patellae.
1157	aging adult	male	Peter	Clarke	degenerative joint disease	Left and right acromio-clavicular joints. Left 1st metacarpal, distal end. Right and left acetabulae. Left distal femur.
1170	prime adult	female	Mary	Porter	degenerative joint disease	Heads of left and right 1st metatarsals, head of right 2nd metatarsal and head of right 2nd metacarpal.
1203	aging adult	male	William	Farmer	degenerative joint disease	Left acromion. Left and right distal femora, proximal tibiae. Right and left glenoid fossae and humeral heads. Right and left proximal ulnae. Left and right acetabulae and femoral heads
1219	aging adult	female	Martha	Burton	degenerative joint disease	Right and left sterno-clavicular joints. Right acetabulum. Left and right distal femora and patellae.
1225	mature adult	male?	Anthony	Falder	degenerative joint disease	Left glenoid fossa
degenerative joint disease 78						
113	aging adult	female	Mary	Bailey	osteoarthritis	Right distal femur
114	prime adult	male	John	Bailey	osteoarthritis	L5
122	aging adult	female	Ann	Webb	osteoarthritis	Right talus, right calcaneus, right cuboid
162	adult	female?	Thomas	Brown	osteoarthritis	C1 and C2. Left talus, calcaneus and 1st metatarsal
262	aging adult	female	Sarah	Hathorn	osteoarthritis	Right distal femur, Right and left acetabulae, C1 (dens facet), articular facets of L4-5, T2, T11.
304	aging adult	female	Sarah	Stockall	osteoarthritis	C1 (dens facet), C2 (dens).
343	mature adult	male	Charles	Stokes	osteoarthritis	Left and right radii, distal end. Right and left scaphoids. Left and right 1st metacarpals, proximal surface. Left and right trapezia. Left capitate, head. Left 1st metatarsal, distal end. Intermediate right cuneiform. C1 (dens facet), C2 (dens), C6
361	aging adult	male	Thomas	Sowter	osteoarthritis	Head of right femur. Right acetabulum. Proximal phalanges of digit 1 (right and left). Distal end of right metatarsal. C1 (dens facet), C2 (dens), C3-T2
362	mature adult	unknown	Ann	Brown	osteoarthritis	C3-C7, T1-L5, Head of 1st metatarsal
454	aging adult	female	Elizth (Elizabeth)	Smith (Smith?)	osteoarthritis	Left distal radius
477	aging adult	female	Ann	Turner	osteoarthritis	C1 (dens facet), C2 (dens), C5-T1, T3-T4.
478	aging adult	female	Mary	Tilford	osteoarthritis	T3-T7, T10-T11
488	mature adult	female	Eliz (Elizabeth)	Rider	osteoarthritis	C7, T1, T7, T12, L5

522	aging adult	male	Laurance	Sidney	osteoarthritis	C2-C3
539	aging adult	male	James	Jones	osteoarthritis	Medial condyles of right and left femora. Proximal surfaces of right and left tibiae. Proximal phalanx of digits 1, both feet, heads of both 1st metatarsals, Right 4th metatarsal, left 1st cuneiform
600	mature adult	female	Catherine	Lowe	osteoarthritis	Left distal femur, left patella, Right femur, Right acetabulum
603	aging adult	female	Mary	Deer	osteoarthritis	Right capitulum, right metacarpo-phalangeal joint and proximal interphalangeal joint 1st digit. Left trapezium and left 1st metacarpal, proximal end. T3, T9-T12.
616	aging adult	male	George	Girsewood	osteoarthritis	Both hands, 5 proximal phalanges, 7 intermediate phalanges, 2 distal phalanges. Left and right scaphoids. Right trapezoid. 1 proximal foot phalanges. Right and left distal phalanges for digit 1, Right and left 5th metacarpal. Distal end of right humeri
619	aging adult	male	Charles	Cole	osteoarthritis	C6-C7, L4-5.
620	aging adult	female	Sophia	Cole	osteoarthritis	C1-2, C5-6.
621	aging adult	male	Thomas	Cole	osteoarthritis	L4-5
626	aging adult	female	Sophia	Louch	osteoarthritis	T6-7, L4-5
655	mature adult	male	Ann	Davidson	osteoarthritis	Left distal humerus
656	aging adult	female	Mary	Williamson	osteoarthritis	Right 1st metacarpal, distal end. Right 1st metatarsal, distal end. L4 and L5
657	aging adult	male	Cuthbert	Wilkinson	osteoarthritis	Right distal interphalangeal joint, 1st digit. Right distal femur and patella. T10-11.
704	aging adult	female	Elizabeth	Willet	osteoarthritis	Left 2nd and 3rd metacarpal. 1 proximal phalanx and 2 intermediate phalanges of the hands.
705	aging adult	male	Thomas	Willet	osteoarthritis	Right 1st metatarsal, distal end.
708	aging adult	male	John	Horton	osteoarthritis	Right pisiform, triquetrum, scaphoid.
713	aging adult	male	William	Prosser	osteoarthritis	Left distal femur, Right distal femur and patella.
724	mature adult	female	Ann	Hooker	osteoarthritis	Right radius, head. Right humerus, capitulum. Right trapezium. Right 1st metacarpal, proximal end. C1-2
771	aging adult	male	Thomas	Dalton	osteoarthritis	C6 and L5
782	mature adult	female	Cathe (Catherine)	Bailey	osteoarthritis	Right and left femoral heads and acetabulae
788	mature adult	male	George	Wright	osteoarthritis	C2 (dens), C3, C5 -T1
812	aging adult	female	Mary	Combers	osteoarthritis	Left distal femur and patella.
831	aging adult	female	Mary	Monk	osteoarthritis	T5
846	aging adult	female	Elizabeth	Lorimer	osteoarthritis	Right trapezoid (scaphoid facet), T3
855	aging adult	male	Trefusis	Lovell	osteoarthritis	Right trapezoid (scaphoid facet). Right scaphoid (trapezoid facet). Distal interphalangeal joints of digit 3 and 5, right hand. Joint of left 1st metacarpal and proximal phalanx. C2-6. T3-T7

858	aging adult	male	Thoms (Thomas)	Dallison	osteoarthritis	C1 (dens facet), C2 (dens), C3-T1, T3-4, T6-12, L5. Sacral superior articular process.
860	aging adult	female	Mary	Lockin	osteoarthritis	Proximal interphalangeal joint of digit 2, 4 and 5, right hand. Distal interphalangeal joint, digit 2 and 5, right hand. Proximal interphalangeal joint, digit 2 and 5, left hand. Distal end of right femur, patellar surface and patella. C1 (dens facet)
861	aging adult	male?	Alex	Bailly	osteoarthritis	C1 (dens facet)
862	adult	female?	Elizth (Elizabeth)	Baillie	osteoarthritis	Distal right femur and proximal right tibia
888	mature adult	male	Charles		osteoarthritis	Right glenoid fossa and humeral head.
890	aging adult	male	Samuel Austin	Fuller	osteoarthritis	Left head of humerus, and articulating area of "new" articulation formed due to subluxation on the scapula.
895	aging adult	female	Hannah	Hickin	osteoarthritis	Left 1st digit, interphalangeal joint. Right trapezium. Right metacarpo-phalangeal joint.
910	aging adult	male	William	Rone	osteoarthritis	T1
920	aging adult	female	Sarah	Fuller	osteoarthritis	C1 (dens facet), C2 (dens), L5
934	aging adult	female	Cathe (Catherine)	Allan	osteoarthritis	C5-6
946	mature adult	female	Lydia	Batty	osteoarthritis	Left 1st metatarsal, head.
951	aging adult	male	John	Stubbs	osteoarthritis	Right and left 1st metatarsals, distal ends.
961	mature adult	male	Edward	Keat	osteoarthritis	Left acromio-clavicular joint. Right and left 1st metatarsal. Proximal phalanges of digit 1, lower limb. C1(dens facet), C2 (dens)
968	aging adult	male?	Jane	Colchett	osteoarthritis	Right acromio-clavicular joint. C4 and C5.
976	aging adult	male	George	Nightingale	osteoarthritis	Head of left 1st metatarsal
980	mature adult	male	George	Lowe	osteoarthritis	Left and right 1st metatarsals. Left proximal phalanx, digit 1 of the foot
985	aging adult	female	Ann	Bateman	osteoarthritis	T1, L5
990	aging adult	female	Elizabeth	Hewlett	osteoarthritis	L5
1009	aging adult	female?	Mary	Clark	osteoarthritis	Left trapezium, articular facet for MC1. Left MC5, articular facet for the MC4. Interphalangeal joint of left and right MC1. 5 proximal phalanges from digit 2 and 3 (left) and 2-4 (right) of hands. 3 intermediate phalanges from the hands.
1062	aging adult	male	Richard	Sumption	osteoarthritis	Right femoral head and acetabulum
1086	mature adult	male	Thomas	Fisher	osteoarthritis	Right acetabulum, left and right proximal tibiae, left distal femur.
1130	mature adult	male	James	Roe	osteoarthritis	Left 1st metatarsal, distal end
1141	aging adult	male	William Charles Fredk (Fredrick)	Patch	osteoarthritis	C2, C6
1142	young adult	male		Wellsted	osteoarthritis	Right and left ulnae, olecranon fossae.

1145	mature adult	female?	Mary	Lan	osteoarthritis	Right and left femoral heads and acetabulac. Right distal femur and patella. C6, C7
1155	mature adult	male	John	Smith	osteoarthritis	Right rib number 9, C2 (dens), C4-C6, T2-T6, T8-T12.
1156	mature adult	female	Elizabeth	Farmer	osteoarthritis	Left scaphoid (trapezoid facet). Left triquetral (lunate facet),
1157	aging adult	male	Peter	Clarke	osteoarthritis	C1 (dens facet), C2 (dens), C5-C7, T5-T7, T12-L1.
1203	aging adult	male	William	Farmer	osteoarthritis	Left and right heads of 1st metatarsals and articulating proximal phalanges. C3
1219	aging adult	female	Martha	Burton	osteoarthritis	Left 1st metacarpal, proximal and distal end.
<b>Osteoarthritis 66</b>

## CHAPTER 6 DISCUSSION AND CONCLUSIONS

*by Angela Boyle*

The archaeological proposals for mitigating the impact of the proposed works on the surviving archaeology at St Luke's were outlined in a detailed Written Scheme of Investigation (Boyle 2000) which ran to 10,000 words. Although post-medieval funerary deposits in general have the potential to yield a wide range of archaeological and historical information it was thought that the resource at St Luke's was likely to be both incomplete and in poor condition. In addition the structural condition of the crypt was very poor. For these reasons it was decided that the resource did not merit full archaeological excavation although it was recognised that it would still be possible to answer questions relating specifically to the group at St Luke's. It was also acknowledged that the resource was likely to further our understanding of the taphonomy of crypts and churchyards and to contribute to the development of techniques for the scientific analysis of human remains from funerary deposits. Therefore it was decided that an archaeological watching brief would be undertaken on the clearance of the human remains by a commercial undertaker with specific objectives relating to the potential outlined above.

An archaeological watching brief had previously been undertaken by MoLAS on five test pits excavated against the exterior walls of the church in order to assess the composition and state of repair of the foundations to the church and the material in which they were constructed. It was not clear from the test pits whether the foundations of the church were constructed in a trench or whether the surrounding material was dumped later. No archaeological levels earlier than the church were revealed. This investigation also suggested that there were likely to be few inhumations in the immediate vicinity of the church. Inhumations were encountered in test pits 1 and 2 and those in the former at a depth of only 0.8 m. Burial vaults were identified in test pits 2 and 3.

A desk based assessment (MoLAS 1996) detailed all existing documentary sources. This was followed by an assessment of the archaeological potential of the site, particularly in relation to the study of post-medieval human remains, and the development of recommendations for archaeological mitigation. (Cox 1997; 1998a). A conservation plan was prepared by Purcell, Millar and Tritton.

Research issues in post-medieval burial archaeology were defined in some detail in a recent monograph dedicated to post-medieval burial (Reeve 1998, 222) and are worth repeating here. It is clear that the relationship between the historical documentation and the condition of the material (both skeletal and artefactual) is a critical one.

- *Funerary archaeology*. Sub-headings include charnel pits, mass graves, artefact developments, taxonomies, social and gender archaeology, the English funeral, ownership and choice of vaults, burials as entities, graveyard methodology, location of interments to memorials
- *Osteoarchaeology*. Sub-headings include palaeodemography and demography, biological anthropology, pathology, epidemiology, osteological methodology (pathology, age and sex, stature), forensic science, clinical medicine, genealogy
- *Archaeological methodology*. Theory and practice, curation procedures and environments
- *Evidence for known historical events*, eg epidemics

Nonetheless there is still no official recognised research agenda for post-medieval burial within London. This is an omission which is currently being addressed by the Archaeological Advisor for the London Diocese (John Schofield pers. comm.) Limited systematic recording of crypt populations or indeed post-medieval graveyards has taken place. Although several clearances have been carried out at London churches only Christ Church, Spitalfields has been subject to detailed archaeological and osteological recording in conjunction with extensive documentary research.

The archaeological resource at St Luke's was assessed according to a series of criteria prior to commencement of work: the criteria were completeness, condition, rarity, historical documentation and group value. The results of the assessment can be summarised as follows:

- **Completeness.** The completeness and integrity of the human skeletal assemblage has been affected by disturbance to the crypt by vandals and grave robbers, thus the potential for detailed population studies is severely limited. Furthermore the

construction work in the churchyard will involve only partial exhumation of the burials there.

- Condition. Conditions within the crypt are very damp and this is likely to have caused the decay of wood, textiles and other materials. Both the coffins and the human remains will have been affected by the activities of rodents, insects, bacteria and fungi. The successive layering of coffins one on top of another may well have crushed earlier burials. It is likely that successive burial in the churchyard has led to intercutting and disturbance to all but the latest burials. The digging of drainage ditches and landscaping will also have affected the integrity of the deposits.
- Rarity. It is clear that other similar assemblages survive in London. Nonetheless the anticipated size of the sample combined with the existing documentary evidence do enhance the rarity and potential of the group.
- Historical documentation. A wide range of documentary evidence exists and this will enhance and complement the archaeological information.
- Group value. The value of the group is likely to be moderate due to the incomplete nature and poor preservation of the assemblage. However, the evidence for this is unclear and remains to be demonstrated by the proposed archaeological intervention. If preservation is as poor as is anticipated it will still be possible to determine basic demographic parameters by employing low-resolution osteological recording. This will facilitate comparisons with similar groups from London and elsewhere.

It is fair to say that a number of assumptions were made regarding the nature of the archaeological resource at St Luke's. It was believed that very few of the coffins would be sealed and that therefore a significant proportion of the interments would survive largely intact but without soft tissue or other organic remains such as textiles. It was also expected that a significant number of the interments would have biographical data in the form of coffin plates. With this in mind it was argued that the resource would have the potential to address a limited number of research objectives as follows:

- Development of the crypt and graveyard through time by discussion of stratigraphy and formation processes on site
- Enhancement of our understanding of post-medieval funerary contexts and the archaeological techniques employed
- Enhancement of osteological techniques through the study of individuals of known age and sex
- Development of our knowledge of funerary rites and the treatment of the dead
- Analysis of the construction, use and modification of the crypt structure.

With the above in mind the aim of the archaeological work was to record and interpret as much detail as possible within the parameters of a relatively rapid exhumation and reinterment exercise. It was expected that the archaeological data collected would contribute to the study of the history and development of funeral trends, the demography of the population of the crypt and that part of the graveyard which was being disturbed.

The objectives of the archaeological work were to record the preservation conditions within the crypt and churchyard, the inscriptions on coffin plates, and recording of the human remains and limited sampling of human skeletal remains with biographical data.

### **The reburial debate**

At the time of the Enabling Works the London Diocesan Fund held the freehold for St Luke's Church and surrounding burial ground. As the church was redundant, the exhumations did not require a Faculty, rather, section 65 of the Pastoral Measure applied. For reasons of decency and dignity, the Church Diocesan Fund stipulated that sealed coffins should not be opened and that such coffins should be sleeved on site and removed for reburial. In addition Home Office directions are required for the removal of buried human remains thus a Home Office order was granted for the exhumation at the church. The Home Office order relating to the exhumation works (dated 21 January 1999) stipulated that the removal be subject to agreement with the Chief Environmental Scientist for the London Borough of Islington.

St Luke's is not alone in having a requirement for relatively rapid reburial of human remains. One of the conditions attached to the Faculty for the crypt clearance at St George's Bloomsbury stated that 'All coffins, caskets or other burial containers recovered intact, that is to say not opened, even if damaged externally, shall remain intact and unopened if reasonably practicable and be reinterred after appropriate recording and at all material times shall be treated with appropriate respect and dignity' and also that 'Disturbed human remains shall be listed, examined and reinterred in accordance with the said specifications and archaeological assessment and at all material times shall be treated with appropriate respect and dignity.'

At St Luke's skeletons were exhumed and then recorded osteologically on site as soon as possible thereafter. Thus reburial actually took place over a period of approximately six months.

### **Recent relevant developments**

Guidelines relating to crypt clearance were recently produced by the IFA (Cox 2001). Although the IFA had previously produced guidelines for the excavation of human remains (McKinley and Roberts 1993), these relate primarily to the excavation of skeletons from earth-cut graves and prior to the publication in 2001 no guidelines or protocols existed for the excavation of crypt material or where soft tissue survived. The aim of Cox's paper (*ibid.*, 14) was to 'set out a protocol that seems appropriate in light of the Spitalfields experience and that experienced by archaeologists involved with the recent dead elsewhere (eg Bashford and Pollard 1998; Boyle and Keevill 1998).

The most recent version of the Archaeology Policy of the London DAC was issued in January 2005 and took account of the report produced by the Human Remains Working Group (Mays 2005). Archaeological contractors are now required to frame their WSIs within this policy. In its executive summary the Working Group states 'If burial grounds, or areas within burial grounds, which may contain interments more than 100 years old have to be disturbed, whether for minor building work or larger scale development, to a depth that is likely to disturb burials, the relevant areas should be archaeologically evaluated. Any subsequent exhumations should be monitored, and if necessary carried out by archaeologists. In the DAC view, there should be archaeological recording in a crypt clearance. A crypt often contains

hundreds [if not thousands] of coffins and skeletons. The health and safety issues are significant and affect the nature and extent of archaeological work. National guidelines are available and continue to be developed. The archaeological project which excavated 18th-and 19th-century coffins in the crypt of Christ Church, Spitalfields in the 1980s has become a national standard of what can be achieved (Reeve and Adams 1993). Early consultation with the DAC, English Heritage and the local planning authority is recommended if crypt clearance is contemplated.

The following recommendations made by the Working Party are particularly significant.

- If living close family members are known and request it, excavated human remains should be reburied
- Excavated human remains shown after due assessment to have limited research potential should be studied and then reburied
- Reburial should normally be by inhumation rather than by cremation
- When excavated human remains are more than 100 years old and have significant future research potential, deposition in a suitable holding institution should be arranged. Redundant churches or crypts (as already done in some cases) provide an acceptable compromise between the desirability of deposition in a consecrated place and the desirability of continued research access. A working party, to succeed the Human Remains Working Group, should be set up to pursue this, looking in particular at funding and at establishing proper working practices.

At the annual conference of the Institute of Field Archaeologists in Winchester in 2005 a session entitled 'The excavation of post-medieval cemeteries: why, when and how? (but not necessarily in that order)' was organised by Jacqueline McKinley of Wessex Archaeology and Simon Mays of English Heritage. The writer was asked to contribute because of her involvement in the St Luke's project as well as a number of other similar jobs in London and elsewhere (for example Boyle 2004).

Archaeological excavation of post-medieval cemeteries is a relatively new phenomenon: until c 20 years ago most burials of this date were subject to removal by cemetery clearance companies with no archaeological involvement. This changed with the work at Christ Church, Spitalfields in the 1980s as archaeologists and

osteologists demonstrated the immense wealth of information that which could be recovered (relating to all aspects of the burials), particularly where the archaeological data could be linked to written records.

There are a large number of post-medieval cemeteries containing an immense number of burials and with ever increasing pressure on land and the need to update church buildings to the needs of the 21st century, growing numbers of such cemeteries (and crypts) are being totally or partially cleared. Archaeologists are commonly being asked to undertake such work, but the levels of recording and analysis required may vary from cemetery to cemetery and archaeologists need to ensure that they are not simply a more 'politically correct' method of clearance. Archaeologists who took part in the session considered what types of information might be obtained and what constitutes an appropriate level of investigation and recording. It was recognised that we need to ensure that our methodologies for on-site archaeological recording not only accommodate the practical demands imposed by exhumation works but also generate datasets of real analytical value.

## Conclusion

The St Luke's project was an extremely challenging one both for the archaeologists who took part and indeed for Necropolis who were the exhumation company. The logistics were complex and it took effort from both parties to achieve an acceptable method of working together. The approach to the archaeology had previously been employed with success at St Nicholas, Sevenoaks, (Boyle and Keevill 1998), the Quaker cemetery at London Road, Kingston-upon-Thames (Bashford and Pollard 1998; Start and Kirk 1998), St Bartholomew's church, Penn (Boyle 2004) and subsequently at St George's, Bloomsbury (Boyle *et al* in prep). The osteological and artefactual analysis of the material from St Luke's has yielded an enormous amount of valuable information on both burial practice and the population who were buried in the church.

1. *Chlorophyll a* (Chl a) is the primary photosynthetic pigment in most plants and algae. It is a green pigment that absorbs light energy in the blue and red regions of the visible spectrum. Chl a is essential for the light-dependent reactions of photosynthesis, where it converts light energy into chemical energy in the form of ATP and NADPH.

2. *Chlorophyll b* (Chl b) is an accessory pigment found in green plants and algae. It is a yellow-green pigment that absorbs light energy in the blue and red regions of the visible spectrum. Chl b transfers the absorbed energy to Chl a, which then uses it for photosynthesis. Chl b also plays a role in protecting the plant from excess light energy.

3. *Carotenoids* are a group of pigments found in plants and algae. They include carotenes (orange pigments) and xanthophylls (yellow pigments). Carotenoids absorb light energy in the blue and green regions of the visible spectrum and transfer the energy to Chl a. They also play a role in protecting the plant from excess light energy and oxidative damage.

4. *Anthocyanins* are water-soluble pigments found in many plants, particularly in the leaves and fruits. They are responsible for the red, purple, and blue colors seen in many plants. Anthocyanins are thought to play a role in protecting the plant from UV radiation and oxidative damage.

5. *Flavonoids* are a large group of pigments found in plants. They include flavones, flavanones, and flavonols. Flavonoids are responsible for the yellow, orange, and red colors seen in many plants. They are thought to play a role in protecting the plant from UV radiation and oxidative damage.

### Project details

Project name	Islington, Old Street, St Lukes
Short description of the project	Oxford Archaeology undertook an archaeological recording action at the Grade I listed St Luke's Church, Islington between July 2000 and January 2001. Oxford Archaeology was in attendance on Necropolis for the duration of the work. The work took place in advance of construction and refurbishment works in order to provide new educational and rehearsal facilities for the London Symphony Orchestra. The work comprised recording of funerary architecture, and the crypt structure along with exhumation of all burials in the northern and southern churchyards, as well as clearance of all the burials in the crypt. A total of 1053 burials have been recorded and removed. Osteological analysis on all the skeletal material was largely undertaken on site and completed in Oxford. The skeletal sample of 896 was divided into high and low resolution samples. The high resolution sample comprised 241 named individuals who were osteologically recorded in full. The remainder were unnamed individuals; for this group basic demographic information was recovered, stature was calculated where possible, a detailed dental record was compiled and pathology recorded where seen. Dental samples were recovered from the named individuals with the aim of refining microscopic ageing techniques. A total of 712 coffins were recorded and removed for reburial. These comprised lead, wood, zinc and iron. A variety of coffin fittings have also been identified and recorded.

ST LUKES CHURCH  
ISLINGTON

OLROO

SITE DIARY

WEEK 1. Start 10/7/00.

Staff :- DAVID SCORG. (man - John Gill)

MON 10/7/00

met Neophtis on site. John Gill on site all day  
- recorded chest tungs which are being removed  
allocated him Ctr no's 1-100 to film no's 1-10  
- other no's can be taken from main lists as needed

Meeting at ABL - 10.30 am - most parties present →  
In brief - the methodology for the excavation has still to  
be decided - no one really seems to have a firm grip on  
how the jobs need to be done (the complication seems to be  
the underpinning work) and discussions re: "temporary sharing"  
v' confining. - I would prefer a general reduction of 1m  
before excavation paper to Neophtis seem to favour this as  
well, - would prob' do away with need for temp' sharing.

TUES 11/7/00

General photo's of church exterior / graveyards taken  
- including shots from outside railings (before hoarding goes up).  
General organisation of site record folders / kit - temp storage  
of some kit in site Agents office as our "cabin" not on  
site till "churchyard compound" set up - pos next week?

WED 12/7/00

Nothing sig' 2<sup>nd</sup> report. - Levit Bernstein on site recording vestry etc

THURS 13/7/00

Levit Bernstein on site again - I helped Neophtis clear

vegetable from inside church for LB. photo's

- Some bone from a few of the boarding plank holes -  
prob' charcoal - contractors will replace in holes - not  
kept by Neapolis or recorded.

Neapolis taking up paving slabs for storage

FRIDAY 14/7/00

photo'd dismantling of tomb 12, ledger stone 13  
lifted but revealed brick lined grave c. 3m deep with  
remains so replaced & will be removed & covered with  
a temporary cover next week.

10.00 am Janet Miller visit to site, told her tombs  
recorded & now waiting on Neapolis works - react as  
necessary. She wants a weekly report - Done by Ang' to  
arrive on Mondays. - Ang' on hold so I will organise  
something for next couple of weeks. Also - run database  
proposals by her before we start using it to make sure  
they are ok.

(Rep' to include activities done & what is anticipated  
for next week)

next week:- Poss - service trenches to entr of church? - Further  
records on tomb removals, Crypt → access - record before  
opened.

Advised Bob Williams :- next week 1st D.S. week after D.S. to  
Adam Bromley, then following week pos need specialists from  
GUARD & 1 extra OAU?

WEEK 2    Start 17/7/00

- Staff :- DAVID SCORSE

MON 17/7

Notes/photos of fully dismantled tombs (tomb 4 base slabs left on as 3m deep brick grave with 2 lead coffins exposed).  
Pre-ex plan of north graveyard site area done.

Site meeting → Roger Wabbes, Peter Mitchell, Tony McBlane (site manager was on site), Roy Lander, Tony Wells, Dennis Jones, Charlie Oil,

Working method :- 1<sup>st</sup> strip 1m depth off whole excavation area, then lift any exposed remains (investigate any grave cuts to 1 foot depth?). Then dig in 2m wide strip right up to church wall to back fill as we go - therefore no need for any temporary shoring except in 1<sup>st</sup> strip at ends, also no need for any different/special measures against church wall.

→ still waiting for E.H. approval on removal of railings to create site access !!

TUES 18/7

Pre-ex plan of south graveyard excavation area done.

(Stone masons starting to remove steps but v' slow going.)

Necropolis will want to "excavate" small area to east of church (services?) before main areas due to access but details of service dig not clear ??

So - any digging in churchyard delayed & probs will not start for a while - when it does should be initially on low level of 600s as only 1m depth to start with & spoil going off site.

WED 19/7

Access to crypt gained via southern vault and from ground level within church down into 4<sup>th</sup> (northern) vault - inspection

revealed arches compromised / cracked - falling against  
northern wall of church. V' poor condition - dangerous!  
parts of arches (cicling) missing etc. coffins covered with soil  
but lots of vandalism, coffins displaced / opened etc. V'mony  
- if floor level same as southern vault - 2 layers of coffins  
- if no burials below floor level pos max of 300 coffins plus  
chancel? remains of earlier burials?

Due to unsafe nature of crypt structure Tony McKale  
requesting it be looked at by H&S / structural engineers etc  
as it is unclear how job will be done (will roof need to  
come off 1st?) (Roger Webber came & had a look PM).

SO:- work in crypt could be delayed - not clear what  
happening.

Work programme generally now in question. Adam booked  
into hotel so it will be DS & AB on site next week  
regardless, but after that we will have to play it by ear  
(will be useful for AB to get to know site / people etc & may  
be some work to do?).

suggested to T.M.H. that we should get Dr Susan Yang  
down early next week to check over anyone who needs it  
now that crypt is open, i.e. AB can be done at sometime

THURS 20/7

Took some photo's of dismantled steps.  
Organised for John Gill to be on site next week to record  
1st (southern) bay of crypt & assess recording strategy for rest  
of crypt.

Bob Wilson / Philip Gunner visit PM & had a look at crypt (Philip  
concerning for B.W. for next 3 weeks) (B.W. said he always thought  
crypt roof would need to come off before work could be done !!!)

FRI 21/7

Peter mitchell visit/inspected crypt. Pm - agreed with Tony McHale that condition is 'dangerous' to work outside in graveyard could well cause it to collapse. He wants to get specialists in to assess it - will be various people coming to site on MON. (Neeropolis not happy - feel something "fishy" going on - poss. they have been "stitched up"?!) over the condition of the structure - were not able to get in to inspect at tender stage etc.) Also no. of bodies - poss. only 200-400, not 900 - not good for v.s. to who means Neeropolis have to sift more spoil than they thought (this to be done by hand!!)

WEEK 3 24/7/00

Staff: DAVID SCORE

ADAM BROOKER

MON 24/7

JON GILL (Mon/Tues)

DS, ADAM B. CHECKED BY DR SUSAN YOUNG FOR SMALL POX TAB - OK.

Jon Gill on site - recording 1st bag of crypt (no burials).

(Neeropolis had a consultant in to look at crypt and advise them on legal/contractual aspects of work)

Tanet Miller - site visit - explained delays/probs etc to said we would go 'off site' till sorted out? - she would be happy with that.

TUES 25/7

Jon Gill on site cont' record of 1st bag of crypt.

JG CHECKED BY DR SUSAN YOUNG - OK.

Pin - lots of people visit to site - inspect crypt - Tony Wells,  
Rob van Hone

Looks like a localised sharing system will need to be  
put in place - I stressed we will need to record crypt  
"as it is" before this goes in (subject to MoS). o's prob' best  
to investigate this ASAP - I said we would need a  
week - Tony Wells said it would take him that long  
to organise it anyway. [I don't think they are  
likely to get anything moving for at least 2 weeks on  
past performance!]

Spoke John Atkinson (GARD) on phone - told him we  
would not need specialists for 3-4 weeks.

We will be off site from midday tomorrow pending crypt recording  
to new programme. I stressed to everyone that I  
thought the crypt was v' dangerous but the 'experts'?  
seem not too worried - just local areas need showing??  
- numerous cracks / holes plugged with caulk etc - bearing  
in mind we will remove him - I saw a spot for  
inside each bay to pan digging (with machine) outside  
I think the whole structure unstable? - But will have  
to go with expert opinion (they're certainly had enough  
different people to look at it now).

WED 26/7 - off site midday.

FR 1 28/7 (office).

Spoke Janet M - Informed we are "off site" today but  
that I am trying to organise JG/DS to record crypt ASAP.  
As regards rest of works - we are "on standby" but I think it  
will be some weeks before we are required on site again.

## WEEK 4 - week start 29/7.

OFF SITE ALL WEEK.

Peter Mitchell has had letter from Ivett Bernstein saying it is safe for us to do record of crypt (providing we do not cause vibration) - our record is photo/drawing/written so should be no prob - he will send us a copy of the letter.

● We will be on site week start 7/8 to do crypt record  
Jon Gill - taken off 'Wobich' to do it - should take max of 1 week.

Spoke Dennis Jones - told him I was happy to accept advice to arrange (based on numerous experts' inspections) that crypt was safe for us to do record but that I would want our independent advisors to inspect H/S of structure before the main job starts & after all shoring measures have been installed.

4/8 Peter Mitchell - working method changed again? - will now be removing all spoil from graveyard digs but in 1-2m spils. - no need for shoring except around perimeter - but still prob of what to do about church wall/underpinning?

## WEEK 5 - week start 7/8.

Staff: - DAVID SORÉ, JON GILL.

MON 7/8

started full record of crypt structure, J.G. doing most of work. DS present for H/S reasons if no other site stuff around. Have 'walk-talk' for constant contact with 'topside'. Starting with completing a full Base plan. Recorded 'ledger' measured in N graveyard site across area (102).

TUES 8/8

Work cont' in crypt. New site safety manager - Francis - raised new concern about safety of crypt structure.

I said I had to go on what experts are saying - at moment the official word is that it is safe - but if it is not I want to know & will need to be instructed officially that I cannot work (I can't just walk off the job as at the moment the project managers are saying it is safe & if I stop work we will not be able to return to complete the record for some weeks due to other commitments - (G Woolich) - this could cause major disruption to program - also any change to record would need to be approved by G.M.) i.e. I need to be 'prevented' from working. But if the crypt is not fully safe I fully expect this to happen. There seems to be lots of different views on it & I need to have a clear official line on whether it is safe or not - meeting then Ann may help to clarify things? [I think if we are not able to complete the full record of the crypt we will need to raise the issue of payment]

WED 9/8

Cont' work in crypt.

Am - site meeting - Peter middlell, Ray, Roger Weller, Francis, Charlie Orr, Denise Jones, Derek Hand, Wachi Turner & various others.

Confirmed we will be furnished in crypt by ERI. Also everyone agreed that no works causing vibration should be undertaken while crypt recording in progress i.e. no machines/diggers, vestry dismantling etc. I stressed again it was important that the work be completed this week because J.G. not available next week, we are not really building things up anyway - the vestry demo would not delay the program even if it happens early next

week. Apart from stronging vibration aspect no-one at meeting said crypt was unsafe (although Francis had said he disagreed with Tony Wells on safety of structure?). I had said over & over that if its unsafe I need to be told officially & I will cont' to accept the official line that it is safe & we will complete our work by Fri.)

THURS 10/9

Cont' record of crypt.  
Necropdis knocking out blocked entrances with hammer/chisel - as H.S. prob with this.

FRI 11/8

Tony Wells & another structural engineer (over up?) inspected crypt for 6 vicky Turner who went in to have a look.

Ann Janet Miller visit - all ok. Told her we will be in on Sat. (to be paid by Necropdis) to record minor dig in S. churchyard. [We are charging day rate of £225 + vat for any work directly for Necropdis outside our normal contract hours.]

1<sup>st</sup> stage of crypt record complete. Further work will be required when cleared.

Apparently next week - stone masons not starting to take down crypt until TUES - should take 2 days?

SAT 12/8

On site - DAVID SCORCE, (subcontracted by Necropdis on day rate basis). Small amount of digging adjacent to South East access - i.e. around ventilation vent - c. 0.90m depth in area of path  $\rightarrow$  0.05m tarmac over 0.20m concrete over pre-existing path slabs over gravel soil. i.e. from 'old' path surface c. 0.25m below present.

WEEK 6 Week start 14/8

Staff: DAVID SCORR.  
(Mon, Tues, Wed, off site.)

THURS 17/8

[Services to east of church will now be done at end of job rather than start]

Necropolis started 1.2m reduction in N graveyard.  
0.3m 'topsoil' 0.7-0.8m 'made ground' with grave cuts visible.  
At base of excavation coming down as construction proceeds?  
deposit of brick/mortar etc - graves visible in this.

FRI 18/8

Reduction continued - about 1/2 of area done - no human remains visible/measured in the 1.2 depth, but some brickgraves & ledgers noted. Also - vault - substantial arched brick - under Vebry area - recorded but appears not to have burials in it.  
- top will be taken off but not dug full next 1.2m spit.

Sadie Watson (ws Atkins) visit am - happy.

About 10-12 grave cuts seen so far.

(May have elec in cabin early next week?).

[Photo of paving at site entrance for Tony McHale - to show slabs already extensively cracked before lorries drive onto them]

WEEK 7 Week start 21/8/00

Staff: DAVID SCORR

MON 21/8

Reduction of N churchyard cut - no skeletal remains in ground seen yet - (most of cut below 1.2m). But numerous ledgers/legends - about 0.3m below ground level - later landscaping? Also → 2 vaults - brick in good condition - poss 5/6 lead coffins in each. Bob Wilson on site → stated he did not want the coffins which were least damaged opened - I said I thought E.H. would want them opened so he must resolve to clarify this situation with them. He will contact Levitt Bernstein, I contacted Sadie Watson at

W.S. Atkins to bid her situation. I need some firm instructions on how to proceed. I suggested a site inspection by all parties concerned so they can agree on how to proceed (this matter has been hot since so far but now it needs to be resolved). I will not do anything with coffins until it is sorted. [elec still not on for freezer & warwick's can work elsewhere so will not hold things up unduly]

### TUES 22/8

Will be a meeting THURS. PM with Bob Wilson, EH, W.S. Atkins etc on site.

started 'reducing' of S. churchyard - slightly more 'made good' above the level of ledgers etc. (Pon an additional 0.3-4m dump or landscaping deposit). - rest of sequence seems the same. lots of brick graves etc - may have to deal with them on the 1<sup>st</sup> spit as will be difficult to come in & track back over. Cannot cont' with N churchyard but scaffolding over vesting area is down - should be born then. (Tony says he will not work with next week if water/dec not on!)

### WED 23/8

Cont S churchyard - large vault found on southern edge of area. N churchyard - scaffolding down & vesting vault (109) broken out - came away eas. to. from main church wall as not tied in to it.

### THURS 24/8

N churchyard reduction cont' - east wall of vesting vault left in (lower part) for now as church wall pos. unstable - cracks appear worse? - Pon talks about trying to underpin the corner straight away?

Ang Bayle, Philip Bird, Catherine Cavanagh (EH), Sadie Watson (W.S. Atkins) & Bob Wilson on site PM. All in agreement about what is meant by "largely intact" & "significantly perforated" - situation re opening of coffins now clear & Tony McHale & I will make decisions on a day to day basis.

FRI 25/8

Sadie will not visit today as came yesterday.

Recorded coffins in vaults 109/110, general reduction cont.

Elec "on" if freezer ok, can start taking out bodies from vaults (DNA if needed) on MON. - (I will work MON (bank hol) on day rate basis paid by Neangolia)

WEEK START 28/8

WEEK 8

Staff - DAVID SCORF

MON 28/8 (Bank Hol)

Trip switch for our cabin elec gone off in main box! - Put back on but will have to watch it carefully - may need bigger fuse? - freezer puts out a lot of heat in a sealed space!?

Cont strip in S churchyard - just remains c. 0.5m over whole area so raised ledgers i.e. → old graveyard level.  
- Removed one body from vault 110.

TUES 29/8

S. churchyard → stripped to west extent - cleaned ledgers etc.

Took further coffins out of vaults 109/110 but 2 of the 3 "largely intact" coffins fell apart & ∴ I retrieved the bones (it seems even if appears fairly good on top the bottoms are bad - will need to check this before removal of future coffins as it makes it more difficult if coffin is opened & bones disturbed & then it falls apart!)

WED 30/8

Plan / description / photo's of S. churchyard with ledgers exposed - cont. reduction of N. churchyard.

New method for working ∴ will complete initial reduce to 1.2m

then work back from west side in 2m wide strips. But go all way to formation & then backfill: can track over backfilled area with dippers/machine & no need for shoring. Tony wants to work both churchyards simultaneously next week to week after - clear N-S access through west end of crypt (should not be many burials in that?) - cannot do anything till crypt shored/made safe etc.

THURS 31/8/00

Cont' N & S churchyard reductions.

Allen build trying to push for underpinning of NE corner of church, - same exec-tive (name unknown) from then gave me a bit of waffle about cooperation to the S. - Sounds like complete bullshit - at the v. least it was v. patronising. I said nothing except that any work would need a full method statement that would have to be agreed by the archaeological consultants (I don't even think the implications of this sank in with him). Tony later informed me he had only involved me in the discussion because Tony had insisted to later, booted about how he had 'dealt with' the archaeologist!! - I await his method statement in a mood of anticipation! These people are trying to circumvent the proper project procedures & will be told what the actual save is in due course if they proceed in the same way. However, Neophili's have now put hold on it anyway as Tony wants to cont' with the exhumation as planned. [Also - Francis informed Roger Webber of Neophili's that I was in full agreement with their plans - Blatantly untrue & again shows they do not understand what is meant by "the archaeologists must approve your method statement".

FRI 1/9/00

wait on S churchyard till concrete next to church

Broken out. N.C. cont' reduce. I have dealt with  
~~burials~~ burials in V. 109/110. but lower level! in V. 110 - per 3 more!

Sadie Watson visit am :- all ok. informed re: method  
Statement etc from Allen Guild - no hurry at moment  
but WS Atkins also keen than proper procedures be  
followed re consultation/method statements etc (no need  
from project management to oversee this, so we will  
deal with it as things arise)

VALUATION = 14 BURIALS.

WEEK START 4/9/00 WEEK 9

Staff: DAVID SCORE SARAH LUCAS

MON 4/9/00

Cont' reduce to N.C. S.L. recorded 'sample' sect. (3) at east  
Side (shows tomb 5, a ledger support to grave cuts etc as well  
as typical graveyard sequence).

In S.C. modern tarmac path removed with 0.25m of make up  
- created 1st paved path incorporating some ledgers - planned to  
photo'd etc.

TUES 5/9/00

S.L. dealing with vault 149 in S.C. - multiple burials in  
single width brick grave.

DS. machining N.C.

WED 6/9/00

end, work cont' - got to end of dig in N.C. - adjacent to church,  
West large brick base? under steps (could be a vault?) and a brick  
drain/soophaway seen.

Sample Sect at west end drain<sup>(8)</sup> - taken down 3.5m to bottom  
of reduce - no other sig' arch' seen but 1 + m of pre-church  
slab.

THURS 7/9/00

S.L. completed removal of burials from vault 149 - SC. - 6 BURIALS.

NC machine / full volume of west end of dig area cont', vault 208 opened - looks like 4 burials? inc' a total/only wood coffin.

clients? drawing site with Tony McHale - same old.

Alan Buitel had their underpinning subcontractor on site (Gallois). Their method statement applies to work as originally planned i.e. - with arch/extension already dealt with. SO I outlined some of the potential problems & stressed that arch work takes precedence over underpinning. I will do everything I can to help things run smoothly but they must realise they cannot just come on site & do the job as they would have originally planned to do - prob's now with access / parts of the site they cannot track over etc. Also I will need to inspect / monitor their excavations. I get the impression they don't think any of this affects them & that is a bit worrying. I have tried to warn them that I will be involved but I think they are prob' being misled by Alambuitel about my involvement i.e.; "don't worry about anyone else will sort it" - they just want their bit done! - prob's with pending payments because the underpinning was originally going to start now but because programme is behind it really should not be taking place for another 4-6 weeks. I have let the method statement issue 'go' on the basis that I have verbally spoken to the contractor, he has outlined how he will work & there are clearly lots of practical prob's which will just have to be solved as we go along - the key thing is that they realise they must consult / be advised by me as regards any effects on the arch work.

FRI 8/9/00

North C cont', trying to clear end at west to provide working area for spoil etc.

clearing vaults of lead coffins.

Janet Miller visit am:- Informed of new underpinning work - she will put documentation in place - will stress importance of arch' H&S etc (may want a revised H&S plan from neophiles to take account of the 2 contractors working side by side) - he appreciates the obvious H&S implications to the fact that arch' could be compromised if contractors are not cooperative. Backs the importance of arch' if it comes to it the arch' will come first (I get impression that it is a requirement of planning permission - EH do have powers here to need to be satisfied)

NEXT (→ Project Meeting Wed + EH visit FRI)

BURIALS THIS WEEK 17.

'31' BURIALS SO FAR ON PROJECT

WEEK START WEEK 10 Wk/Start 11/9/00

MON 11/9/00

STAFF: DAVID SCORE

SARAH LUCAS (mon-wed)

BON FORD (THURS/FRI)

Concentrating on N.C. doing full redirection at west end.

TUES 12/9/00

multiple burials in N.C. graves, although area in front of NW steps is clear (no burials)  
- clearance of spoil/rubble from 1st bay of crypt underway.

WED 13/9/00

AM MEETING (main project meeting for month)

I will now get our independent H&S consultant in to look at

crypt. we have 3 weeks from next mon to complete  
excavation/reduction of N.C. before undertakers come in (rather  
than clear a 5m strip next to church (would have been 2 weeks  
- acceptable estimate! - but I said I thought that was too tight).

[Anna Richman (Hertford Learning Fund) visiting site. FRI 29 Sept]

→ next project meeting 11th OCT.

West end strip complete - dangerous sides - c. 3-5m at edge  
so some bodies taken out with machine bucket but still good  
% of bone retrieved & in fair condition - acceptable method  
in the circumstances.

THURS 14/9/00

Spoke Alex Wood from our H/S advisers, explained situation - he  
will get back to Bob Williams or me.  
Machine - N.C. broken - fixed by 11.30 am. Difficult to machine  
through due to spoil dumping & machines cannot sit next to church to  
pull E-W - have to pull N-S - means 'across' bodies so  
collection more difficult.

Bob Barton - engineer - arranged visit for next TUES - meet  
Tony Wallis on site - to inspect crypt on our behalf, explained  
situation to him. T.W. will send him scheme of work today.

FRI 15/9/00

Ang Boyle on site

Trucks loaded at start of day but heavy rain prevented  
any excavation work - site completely unworkable.

AM - Janet Wallis, Jez Reeve, Cathie Cavanagh visit  
to site - seemed happy.

36 BURIALS RECORDED THIS WEEK

(67 IN TOTAL)

WEEK 11

Wk start 18/9/00

Staff: DAVID SCORSE. DAVID HALL (TUES-FRI)

JULIE ROBERTS. MEL RICHMOND.

MON 18/9

David Hall sick.

Julie R / Mel R on site - NC continued, crypt - vault  
(251) structural burial dealt with - clearance of crypt now  
reentering coffins - Necropolis clearing around them & leaving  
them for us to deal with.

Ang sick so not coming down today.

TUES 19/9

David Hall on site - instructed re: systems / methodology and set  
to work in NC - he will be responsible for this area  
- should be able to handle it on his own with occasional  
help as needed.

Mel - recording burials in crypt.

Mel checked by Dr Susan Young - OK. Out, Julie / David H no  
Jobs for Smallpox so no crypt work.

Bob Barton (our structural engineer) visit a.m., Tony Wells  
Dennis Jones, Necropolis, Nick (Allen Build), Francis Mennigeller  
~~Bob~~ Peter Mitchell. (Susan Jones also present)

Bob Barton basically agreed that crypt is safe - agrees  
with Tony Wells / drop monument - arches basically sound,  
methods proposed to 'deck' the east ends are OK. But  
he suggests 'monitoring' via pins in arches - this agreed  
by anyone & will be put in place.

A possible alternative method proposed by Francis to  
both schemes will be costed etc, (if diff Bob Barton may have  
to check again) but now only discussing the details of the  
method rather than basic principle of 'where' staking needed  
& is rest of crypt safe? Myself & Tony McHale agreed  
that with 3 structural engineers agreeing we must be safe.

to proceed. BB will fax us a repair letter and copy to Tony Wells.

WED 20/9/00

Ang can still not get down - will be down tomorrow but in meantime has briefed Julie on bone recording, so this now underway.

NC - proceeding under David H. supervision.

JR MR & DH completed H/S forms - returned to Francis.

THURS 21/9/00

NC cont' DH coping well.

Crypt cont record coffins as they are revealed. - work to remove spoil going quicker than expected & workers doing an excellent job of cleaning round coffins, preserving name plates etc.

Ang down → installed computer for site data base & briefed specialists.

FRI 22/9/00

Work in NC / crypt proceeding as before.

Bob Williams (conv) visit to site - agrees on higher staffing levels etc. (prob. could still be finding appropriate people with small box jobs).

Tanet Miller visit (met Bob W) happy, requested I include running totals of dust samples in progress reports (I objected as not really needed but she needs to show she is doing something for Margaret Cox so I agreed - although hopefully she realises now the job is underway proper. I do not have time to waste on too much PR stuff) (Ang confirmed that Margaret Cox was studying only a small site issue to MC does not need constant updates.)

BURIALS THIS WEEK = 73 PROJECT SO FAR = 140

DNA SAMPLES PROJECT SO FAR = 13 OSTE' RECORDS 34.

WEEK 12. wk start 25/9/00.

MON 25/9/00

STAFF. DAVID SCORE, ANDY NORTON, DAVID HALL (MON-THURS)  
JULIE ROBERTS, MEL RICHMOND.

N.C. cont' with both DH & AN dealing. AN. done  
H.S. form...

Crypt spoil clearance proceeding at speed (Necropolis working  
till 9pm to remove spoil. outlay) we are keeping up at  
moment but will need extra person next week definitely.

[NB: speed of work is above what we would be expected to achieve  
according to the proposed method - i.e. 7.30-5.30 outlay - But  
this does not present too much of a problem providing we can  
staff up - they will get ahead of us a bit during this week  
though.]

N.C. machine not working this due to staff taking out  
generator. (pm)

TUES 26/9/00

Joint meeting rang :- meeting FRI at 11.00am - site bar  
followed by project review.

N.C. - cont' with AN/DH. - 2 staff should enable this to  
proceed at speed :- no archaeological delay - the job is certainly  
going at the optimum speed as far as we are concerned.

Crypt - recorded some vault serials with MR but felt  
ill - faint / headache etc - others also complaining - poor  
machine (gas operated) for Ganspohr, fuel to flame - raised

thru with Ray Lander - he will require of the hire company to get their literature - also working on improved ventilation  
- Hire co. man says only emissions should be CO<sub>2</sub>

WED 27/9/00

NC continued - burials v. dense towards middle of area, (eg. 14 burials in 1 machine pull ie. 2m x 4m down 3.5m).  
AN/DH dealing.

crypt continued - vault 13 broken into (one of very few not already open) - 1 burial (SSO) - (SF A viewing under thin coffin kept.)

mentioned to Tony Mott / Ray that monitoring pins for crypt still not in place & urged action. Tony also pushing Francis on the shoring works to crypt.

THURS 28/9.

NC cont' - 2m bucket on 360° excavator means each 'pull' area is fairly large - up to 4m long x 2m wide so quite a few bodies can be exposed in one scrape meaning a long wait for the machine - but this is a pocket of exposing a large area. Backfilling & spoil management also takes quite a while so it is swings & roundabouts as we are standing around waiting for them a lot of the time (sifting a 2m bucket for bones also takes some time to throw things down). But overall the job is not held up it is just that each section of work is longer rather than back-to-back between one & next.  
crypt - cont' - appear to be coffins buried below floor? level - at least in Bay 2.

pm - meeting with - Francis (Tons) / Roger Webster / Garry Mott  
cc Harris / Tony Wells - Bob Thompson (Systems Geotechnique)  
01704-823376  
mobile 07977-039618

- suggesting piling rather than underpinning. But would need access to S side of north wall. would need to 'prop' crypt? - I said I would not be happy working anywhere in crypt while this went on with machine working overhead - also comment 'prop' until coffins cleared - so sand & like a 'no go' unless will happen after crypt cleared & this extends rather than shortens programme time.

FRI 29/9 (DH - OFF (doctors)).

N.C. - delay am due to probs with machine but then cont' as usual - burials dense so progress correspondingly slow. (DH - doctors so off all day. AN coping perfectly well.)

S.C. Tony wants to start opening vaults etc so we will do this on mon. - one clearing 1.2m from E end to woking round structures.

Crypt - work continued - recorded further burials - as of next week we will start major clearance of the main bags (we have removed 'overlying' coffins already).

Am - meeting - Janet Miller, Margaret Cox (Julie Roberts, met Richard, Catherine Carmanah) Anna Richie also site tour before leaving prior to meeting).

\* N.C. Bone preservation better than expected - could be worth recording to a slightly higher resolution - Jim asked us to devise a scheme for this to cost it. (Julie will think about it & discuss with Ang Boyce).

\* Soil samples - Jim requested more soil samples to assess taphonomy of churchyards. I will take a no. of samples 3D located from churchyards to add description of location (context not really important as they are not being recorded in that way. - They

will need micrographing / chemical analysis. Also  $\rightarrow$  to characterise the burial conditions of the bone assemblage.

\* Crypt  $\rightarrow$  MC upset at fact that only c. 50% of crypt burials will be taken at (on present small sample) - This due to not opening sealed / largely intact coffins to poor preservation of a few other individuals. JM / MC will tackle church again about changing this. If successful & funding can be obtained (we will charge more for extra work outside the original design). we will need to organise work has to go about this - its fairly complicated I am going to 'hold' on this until church agreement obtained as Bob Wilson likely to object to we need to know exactly what we are required to do before I can make any attempt at working out what its actually means for us in terms of deployment / org / cost etc.

Generally JM happy with the job we are doing.

STATS FOR WK :- BURIALS 90. (Project so far 230)

NAMED 42,

DNA 6 (19 so far)

BONE RECORDS 31 (65 so far)

VALUATION 216 (But 2nd invoice included wk 9  $\therefore$  Invoice will be for 199 BURIALS)

Burials = NC - 174 SC - 6 CRYPT - 50 (24 Bones kept)

Named = 42 - NC = 11 Crypt = 31  
(62% of crypt burials named)

DNA = 19  $\therefore$  45% of named have DNA sample

Bone records working out at 9 per day.  
(4 of 65 are high resolution)

WEEK 13 start 2/10/00.

STAFF - DAVID SCARG, ANDY NORTON. DAN SYKES

MGL RICHMOND DAVID HALL

DAN McCONNELL (SICK ALL WEEK)

MON 2/10

Dan McConnell Sick,

N.C. cont' as normal. AN/DH.

Crypt. Dan, S. JS, MR. dealing.

(No one recording as AN having to cover for Dan Mc in NC.)

TUES 3/10

Dan McConnell still sick,

N.C. cont - moving along wall - large crack, Necros' (under Tony wells instruction) do not want to expose a large area of it. so need to turn and put in small widths against the wall - will take a lot longer & not so good for archaeology but we will just have to live with it. will only be for this fabric location then back to normal. (2hr delay for long loading etc).

Crypt cont.

Spide Francis's about putting in "pin's" to repair vaults - he is obviously prevaricating. I said this must be done as the independent structural eng' for one had recommended it & Tony wells agreed - it is deep/quilt to do & I said I will not walk in there unless it is done - otherwise we are not covered in the event that something happens. I have mentioned it a number of times & now I was U's assistant, he asked me not to bring it up at the forthcoming site meeting & I said I wouldn't. Parading that he understood I won't do it. Tony McKee agrees & will try to initiate something. (I also told Francis he must confirm with Tony wells exactly what is required)

Delay in getting spot lights sorted for pasture area recording (crypt is now lit well with light bulbs but we need extra lights for photo's etc) - 2 statues on cliffs in middle of Bay 3.

WED 4/10

Dan McCannel still sick.

NC, continued - Tony McHale says he will stop on NC now & start SC full redress instead? - wants to let underpinners get established? - I said this sounded a little dodgy. - (I still don't think we will be clear of regimed area by end of Feb).

crypt - cont. as normal.  
SC got near to open up vault (293) on SC - numerous burials 7/8?? not vandalised but will be difficult to disentangle (though preservation good so needs a thorough job).  
- we will switch priority from crypt to SC in clear way for SC work next week - crypt have plenty of work to do so this will not hold them up.

THURS 5/10

BAGS FOR HAND OVER TO NECROPOLIS:-

265	321	264	229	325	296	288	328	310
290	222	250	360	316	266	283	233	292
241	223	244	346	258	234	294	278	277
359	224	347	243	314	282	286	295	249
345	262	348	256	327	293	226	276	242
280	338	349	227	315	252	279	261	297
271	275	280	217	237	236	273	246	
228	326	271	257	285	287	324	272	

List of bags handed over PM today.

70 BURIALS

NC - cont' → saw full depth of foundations against church wall  
- not built on natural - just brickwork on Post med garden soil - c. 4m below ground level.  
- Neco want to get at least the 5m strip along side of church to working done 1<sup>st</sup>.

SC : opened vault 1483 & cleaned it.

Crypt completed vault 1251 so Bay 1 now fully clear of burials?

- NAILS FOR MONITORING OF CRYPT ARCHES FINALLY BEING PUT IN.

Dan Sykes old boy Susan Young for small box Tab.

FRT 6/10

NC - cont - not quite finished 5m strip against church but can be completed now. (nails to be done so scaffolding can be put in).

SC - Vault 1496 - began clearance - v well preserved wood fittings on upper coffin.

Crypt - recorded more coffins from Bay 3. The softy works is "Crashdeck" kit has arrived but it seems to be not tall enough to far to bearing for necrop. personnel to manoeuvre into position - design requires 'fat' to sit on ground! - will clearly have to sit at "primition level". (drawing for design does not show this)

FIGURES FOR WK :- BURIALS: 101

NAMED: 20

DNA: 14

BOXES: 0

RECORDED

} will have to recalculate next week as some records still to be added.

Ann - meeting with Janet Miller - all ok but told her OAU would not undertake the opening of sealed lead

Coffins on moral/ethical grounds, irrespective of the obvious logistical prob's of organising this at a late stage (a situation bound to lead to a "botch job"). We always understood that this was 'fixed' as a principle by directives from the church representatives - & 'review' of project did not include a review of this aspect.

Derek Hand visit to site Am - went over plans etc & gave him info on brick structures & vaults/crypt - he needs it to assess costs for recap charges for removal as there are extras. I had agreed previously to provide this & recap' are aware that I am doing so.

WEEK 14 Wkst 9/10/00

MON 9/10

Staff:- DAVID SCORE, DAN SYKES, DAN MCCONNELL,  
DAVID HALL <sup>(FRI & SAT)</sup>, & ANDY NORTON (MON, TUES, WED & DAY).  
JULIE ROBERTS, MEL RICHMOND

N.C.:- cont' to work just west of vesting vault

crypt:- cont' remove burials (rather than work on S.C. vaults as very heavy rain most of day.)

Game figure of 115 lead coffin burials so far to Tony McHale, Derek Hand & recap GS.

TUES 10/10

NC:- work not start till 9.00am as lorries being loaded.  
- completed strip next to church as far as vesting wall.  
S.C. completed vault 196 - appears to be a combination of earth/vault

burials from same family with revised family ledger used as roof  
for vault / brick-grave. - could be further lower earth burials but  
these will have to wait until main redoubt & then lift in the normal  
way.

I opened vault  - planned / photo'd.

crypt: Recorded a further 3 burials. - need to be v. spec. about which  
burials we have done for 'recof' as they had started to move  
one we had not recorded but generally they are v. good.  
end of day - T. McKale informed me crypt now 'out of bounds'  
to everyone until T. Wells has checked it. (Tomorrow?) - Reason is  
the foundation / burial level can now be seen to be below the  
bottom of the internal crypt wall foundations - does this make the  
walls / arches unstable (I have always raised this as a potential  
problem - especially with soil being removed unequally from  
either side of arch supporting walls.) Engineers have always seemed  
O.K. with this but I am not sure if they really appreciate  
the depth of the walls or the level of work proposed.  
crypt is also getting quite wet & arches are dripping with  
water - combined with the cracks etc. I am as worried as  
ever.

The Support System seems v. cumbersome & difficult to erect  
& at the moment is being put in resting on the ground -  
Something which has always been said is not acceptable  
as reduction / coffin removal needs to take place. I need to  
check if effective monitoring of the pins in the arches is now  
taking place as the hassle to get them put in makes me  
wonder if anything will be done about it. (I have already  
asked Ang' to write requesting confirmation of the points raised  
by Bob Bolton so we have done everything we can)

WED 11/10

[Andy Watson  $\frac{1}{2}$  day & off for rest of week]

NC. Continued.

SC. Cleared vault  - 6 burials - wood coffins.

crypt - cleared 2 burials from west end (bag 2) - waiting on T. wells' comments on wall stability but Necropolis going to clear along base of one anyway to see what they are dealing with.

THURS. 12/10

NC continued.

SC opened brick-grave 126 - suspended lead coffin on iron bars - with complete record book.

crypt - recorded a number of burials

Necropolis finished at 3pm.

Project meeting (am). (NEXT MEETING - WED 8 NOV)

no probs with work being done, NC. cleared far enough for underpinners etc.

QV of demolishing crypt prior to full exhumation being complete seriously raised - prompted by the idea that coffins are below level of base of crypt walls - This is unknown although I think this would not be a major prob - Necrop. team to get crypt down anyway because temp. shoring is such a pain to put in that this now seems the lower of two evils. Foundation level seems to be at about the level of the base of the arch dividing walls base (brickwork). There are then set on a concrete foundation which sits on brickwork. Coffins (best level seen so far) seem to be just below foundation level - any digging below foundation will need to be backfilled with "weak mix" concrete.

Bob Wilson went into crypt after meeting & took exception to a coffin which we had decided to open - I inspected it & it was clearly in poor order but BW. argument seemed to be that we had not inspected & established this thoroughly enough before opening it. As he was not there when this was done I think he is basically trying to throw a bit of weight around. But to note

sure that we are sticking to what was previously agreed. I was fairly annoyed, as the implication is that I am bending to pressure from the archaeological side to opening extra coffins - this is certainly not the case & I said to BW that I had v. recently told Janet Miller & Margaret Cox quite clearly that we could not open more coffins. (something W.C. was keen to push for) because the church would not allow it. It may be that BW realises this promise to not wanted to make same sort of point to make sure I was still carrying out the job according to what was agreed. - insulting none the less!

FRI 13/10.

NC continued.

SC cleared brick grave 126 (46 burials)

Crypt - no action.

Janet Miller site visit, Ang B, also present.

- Discussed increased levels of bone recording - Ang will sort
- = Pos of crypt demolition - wait & see
- = Sealed coffins - no action needed.

FOR WEEK:-

BURIALS 76

NAMED 24

DNA 21

BONE RECORDS 41. (5 named)

WEEK 15, WK/ST 16/10/00.

Staff:- DAVID SCOTT, ANDY NORTON, DAN SYKES,  
DAVID HALL, DAN MCCONNELL,  
JULE ROBERTS (Mon-Thurs) MEL RICHMOND (Wed-Fri)

MON 16/10.

mel Richmond - sick

NC continued.

SC no action - vaults cleared - now waiting on start of full  
redox.

crypt - continued - now concentrating on clearing west end of  
Bag 3.

also - coffins revealed below floor level in vault (240) in  
Bag 1 but no sign of other coffins below floor elsewhere  
in Bag 1??

TUES 17/10

mel Richmond - still sick.

NC continued - Birch grave (597) bottomed → 3-6m below G.L! (2 burials).

General photo's of N.C. / S.C. done to record site.

SC - no action.

crypt - concentrating on Bag 3 west end - going well, 12 burials  
dealt with - preservation of underlying coffins v' poor. Having to  
deal with greater % than upper layers - trying to get some out in  
tact but they have fallen apart - makes it even more difficult  
to retrieve bones properly. Dan S & Jan Mc Connell in crypt - Dan  
doing paper work / cleaning etc. D.S. doing actual bone removal.

NB: N.C. also recorded 'well'? - truncated by grave yard construction?  
burials overlying it. Backfilled with rubble.

WED 18/10

(mel R back at work)

NC cont' but long delays as machine unloading lorries - underpinning  
equipment? [underpinners around area but just seem to be 'setting up?']

crypt - moving ahead well - cleared coffins from west  
and of Bay 3 + recorded vault 18 burials (2) - this  
completes this sect of Bay 3 as long as no other coffins revealed  
when we get to their final clean up.

- started on Bay 2 - working from West end in 6-8 ft  
strips, which will need to be backfilled to formation level  
before we can proceed to next strip (backfill with weak mix concrete)  
→ Pointed out that long spalls on safety frame should be on outside of frame!!  
obtained value of 20.90m for T.B.M. on floor in doorway  
from SW church lobby through to main interior of church.  
Got this from Francis who says Victor Shaw confirmed it was OK.  
Transferred a value of 17.70 to crypt.

Worked out value of Ordnance Survey B.M. on SW corner of church  
to be 20.68m → This will now be used by everyone on  
project, so even if turns out to be incorrect everyone will be  
using the same "site datum" [see note on 26/10 - these figures  
are wrong - Francis gave us wrong figures]

NC - main machine is being off hired to underpinners - so we will  
have to complete retraction/lockdown with small machine - it looks  
on Church the question of remains in the vault under the vestry  
is being ignored (I don't think people want to make waves / create delays  
etc). I have pointed it out although I think remains turning up in there  
is a v. small possibility. The bottom line is that the underpinning gets  
priority over everything because they have been smart enough to  
build in penalty clauses if their work does not go according to plan.

THURS 19/10

NC - Cont' - nearly finished in NE corner - will just leave strip  
next to vestry wall to up to chest tomb B1.

Underpinners have apparently "walked off" saying they will not  
do the job!! Their company is sending another crew on Mon!!?

- No idea what is going on here - it all seems totally farcical to me!!

crypt - cleared 1<sup>st</sup> strip of Bay 2 → not waiting on concrete, so moved

to Vault 2200 - Bay 1 - cleared 7 coffins.  
Sally frame now has supports on outside of frame as well - looks v' heavy??  
Necropolis want me to tell them location & whether Pb coffin  
or not for all the bags we hand over to them! - I said  
no prob' - I can do this from our checklists.

Asked Amy to sort out Jon Gill to come down mon' to update  
buildings record on crypt - need to do this so he can see  
foundations etc before connected over.

FRI 20/10 (Julie R. = Hol.)

NC virtually completed with exception of area under vesting  
& area immediately to east of vesting.

Crypt:- continued, removed some burials from east end of  
Bay 3 - we are basically fully up to date in  
crypt & are waiting basically on 'Necrop' to concrete &  
erect safety frames etc. Generally progressing v' well.

TBM for SC = 20.95 m } nails on hoardings  
TBM for NC = 21.25 m } - These figures  
are wrong  
- Francis gave us incorrect datum.

Bm on SW corner of church = 20.68 (see previous note).

Ric Tyler down mon' to update buildings record (Jon Gill not  
available)

Sko Meeting Am → Janet Miller / Jez Reeve / Catherine Kavanagh  
Seem happy - Jez may be able to put us in  
touch with architectural historian familiar with London who  
may be able to help with info on crypt construction.  
FIGURES BURIALS = 159 NAMED = 53 DNA = 31  
BOWIE RECORDS = 25

WEEK 16 WK ST 23/10

Staff:- DAVID SCOTCH, ANDY NORTON<sup>(4 1/2 days)</sup>, DAN SYKES, (Sick Thurs)  
DAVID HALL<sup>(mon-wed)</sup>, DAN MCCONNELL<sup>(Sick wed)</sup>  
MEL RICHMOND, JULIE ROBERTS

MON 23/10

(JULIE/MEL ARRIVED - 11.45am)

Crypt - we are totally up to date with exposed coffins -  
cont' in Bay 2 to expose/remove more coffins. Also dealt with  
3 in Bay 4 as we need to find extra work to keep busy.

S.C. - Tony had wanted to fully exhume - remove spoil and put  
retention system in - but shoring not ready so he agreed to  
start anyway - cleared rubble etc from east end & started dig.

TOTAL BURIALS FOR NC (so far) = 384

TUES 24/10

DAVID HALL PUT ON FULL TIME OSTEOLOGICAL RECORDING - Julie  
to train him up.

S.C. Andy can cope with S.C. alone - not work coming up in 1st  
strip (prob. due to 'pathway') - Birch grave right on dig line had to  
machine what we could - too dangerous to enter excavation.

Crypt - Going well - fully up to date but prob' is keeping numbers up  
as not many being exposed at moment. (recap' getting ready  
to concrete 1st areas)

NC → underpinning - They have opened a pit 6.5m against the  
middle of the church wall! - 2m out from wall (plus 1m  
all round of strip) - directly in line with main crack - shows  
west side of church wall on birch earth & then gravel where east

side sits on made ground  $\rightarrow$  coincides directly with the point at which the church has subsided at the moment pit only open to 0.8m below base of church wall - they are 'sheeting' it so I have done a quick section to photo's, plus a few sample sections should be enough to characterise the deposits if there is nothing significantly different, looks like visibility/penetrability of underpinning pits will be fairly limited. not sure at the moment how deep they will have to dig but I assume they have to go down to ground all along.

WED 25/10

Dan McConnell Sick.

Crypt - Dan S. checked west end Bay 2 - no more burials.

- started at west end of Bay 4, Steve engineers say this is completely safe.

I note monitoring not in place in Bay 4! - I have had a rant go out Francis over this - totally unacceptable - he has had ages to do it - completely ignoring the project instructions. He says he needed advice we were going to work in there - this is rubbish the monitoring was supposed to be done anyway to specify what needed to be in before work started.

- I am proceeding on the basis that engineers are adamant that it is safe anyway but I am insisting on the monitoring being done - especially as the underpinning leave opened a large pit against the North wall. - we will clear the initial coffins right at the end but that is it. In Bay 2 - we are still waiting for the support system to be moved forward so we can continue work - looks like things are grinding to a halt in the crypt - we need protection to proceed to it does not appear anywhere near ready.

SC - cont' - completed 1st strip & did sample sect/photos/samples etc.

- not many bodies in this end - pathway.

T.HURS 26/10

DAVID HALL & DAN SYKES SICK

There is a general flu/bug going round - lots of people generally feeling ill (the enclosed spaces / hot air blowers etc mean anyone is catching whatever is going around)

Francis has given me the wrong level for the site datum - I am furious - (I checked with him & pushed him as to its validity when he originally informed me) - The true height in the SW church lobby floor is 21.08m NOT 20.90m - I will now have to go thru all the records (we have reduced about 600 levels on the info he gave us) & change everything - this has cost us a substantial amount of inconvenience & quite a bit of time & money. Combined with his inability to get the monitoring done (deliberately ignoring what he was supposed to do - as a 4/5 time I consider this v'serious) & the fact that protection systems are not in place plus he failed to inform us (I now think we were actually del. being misled) about the true nature of the underpinning work - ie pits are 6+ meters long not 1.2m!! - massive holes, total mess of the NC. - had this happened while we were still assuming it would have been a disaster.

crust → Formation level has changed - 75cm lower, but they were still too high anyway (I may be wrong in mind they thought they were too low!!!) - They actually need to reduce about another 30cm - This is also a Francis code up - I pushed him on where the formation level was ages ago & he mumbled something vague about it being at the base of the wall - even the old land is a good 20-25cm below that!! - You just can't get a straight or honest answer to any question you ask an

this project!!

The extra digging in crypt shows clearly that the structure is built on a truncated bridge-like horizon (at least at the west end) with plinths of foundation (rubble/stone) with wood beams between them - possibly originally surrounding/containing them & the wall is then built onto on these. •• no trench building of internal crypt structure apparent from pointing the base of the foundation plinths (not fully clear).

FRI 27/10

DAVID HALL - HOL.

ANDY NORTON  $\frac{1}{2}$  DAY

→ No progress with getting working areas made safe in crypt. So told T. McKee I need to know whether this will be done by mon as I will need to lay staff off the job if there is nothing to do. → I had already received this issue on Wednesday & nothing is happening. I think we need to raise the issue of extra money/claims with the diocesan - this job is not proceeding as outlined & if we do not receive accurate info or advice it is going to cost us a fortune in staff & other costs. T. McKee will speak to Francis re: safety system & get back to me. - says yes - should be able to work in Bay 2 on mon. I will go on this basis because even if nothing is done we can work under the existing protection system & clear the coffins before it slides forward rather than after (although we will only be able to go so far).

Also Andy to send off 2 letters - 1st re monitoring system

- only hot in place in Bay 4 after I have complained again to  
don't think it is properly in in Bay 3. - This is sitting  
out of order, asked my also to ask for comparison  
on other parts of S.B. & letter as we cannot proceed until  
this cleared up.

Also to write to bring up question of delay caused by  
softing system installation - i.e. if we have to stand down  
will need notice to staff back up again.

N.C. enterprises want to dig next pit in area of vesting -  
said must be done under archaeological supervision they said  
they would start today - but by end of day they have not yet  
begun.

S.C. continued dig.

C4 Film → apparently the C4 documenting an excavation is going  
ahead & the client etc have approved it? - we were not  
consulted even tho we are involved in most of the work  
areas on site & are mainly dealing with the 'examination' of what  
God is.

Tony said our views will first be listened to & then to the  
Director etc. I made my reservations clear - I don't really  
want the actually excavations filmed (at least not our  
workman's). They say we can make it clear if there is  
anything we don't want filmed & they won't. They also want to  
take to staff & I said this would be a matter of personal  
choice - but people's wishes must be respected. Bob is that  
the director clearly wants to include material of things which  
can only come from the archaeological site. (I also don't  
want any part of the management of the site (my involvement) filmed  
in my conversations with Tom or staff etc.

I think it is very ill advised on a project with so many problems  
& on a seriously contentious issue of removing burials & arch. & I have  
made this clear to Janet Miller.

Jim visit - all ok. She is waiting for costs for extra work but  
my tells me she was waiting for Jim to come back with comments  
on the proposals.

Francis has sensed that I am not happy about delays  
on safety system & about the monitoring (added to him  
giving me the wrong datum) & he made a deliberate attempt  
to create friction / counter this by saying that the arch's  
had caused 'delays' to the calculation in etc. Tony McHale  
backed me fully to say this was rubbish - I was furious  
as this clearly shows Francis has no idea what the  
job (a joint operation) was about & how it was supposed  
to work, not to mention that it is none of his  
business anyway. He is clearly a v. divisive character & is  
not trying to come probs to deflect attention from his own  
probs. Luckily T. McH. can see that & he is quite happy  
with the way we are working.

### FIGURES FOR WEEK:-

Burials = 57

Named = 19

DNA = 10

Bone records = 17 ~~XXXXXX~~

VALUATION FOR WK'S 13-16 = 393 BURIALS

WEEK 17 WK 16 3/11.

Staff:- DAVID SCORE, DAN SYKES, DAN MCCORMELL (TUE LUNCHTIME - FRID) " "

DAVID HALL (TUES LUNCHTIME - FRI) [BUT MARKED AS FULL WEEK]

MOL RICHMOND

JULIE ROBERTS

MON 30/10

[Dan Sykes, Dan McCormell, David Hall, not in due to traffic chaos  
& trains not running due to storms etc.] M.R. & J.R. in at 11:30?

Tony has confirmed - no grave yard work today as ground

is very wet & it will be dangerous, I agree with this.

In Aug - They want to start installing softing system in Bay 4 but this will apparently mean digging trenches either side & removing effluent? I said I was not inclined to work in there without protection (catch 22) but as scheme was supposed not to impact on burials this problem has ~~arisen~~ arisen because the system was changed with no regard to what people had been told about archaeology. I will have to take advice from the consultant etc on whether I can let these burials go unrecorded - I am not prepared to compromise H/S & although engineers have always said west end of Bay 4 is safe. It was agreed that a system would be put in place anyway & that is the basis on which we were going ahead (especially with the underpinning not being done to the original spec & involving much larger holes).

Figures for Aug's costings on extra bone recording - so far (up to valuation at end of wk 16).

438 unnamed, bone collected burials have been listed.

120 of these have already been recorded (low resolution).

∴ 318 burials (already invoiced for) will require higher level of recording if this is approved.

80 BURIALS

TUES 31/10

Don, Don, David H - arrived lunchtime (1/2 DAY). - S.P. says make them  
 Ilie R - sick. down as on site for OAV  
 record purposes

no digging in SC

crypt - swamp guy confirmed it was safe to work where we are  
 in Bay 2 - (some extra work to be done but this does not affect

where we are preparing to work internally) - will clear vault in middle at E end to 2 coffins on floor then work in from the centre back to the E end.

I have said we will not work in Bay 4 without safety system - we will remove coffins from the side benders (beg. to install safety system) as they are removed to Bay 3. Dan/Dan started work in Bay 2 vault.

In NC digger overturned while lowering framework into underpinning pit on NE ~~corner~~ of church. (depth of vestry vault noted but no burials - this structure was never used - just for made ground noted to reexp. foundation level.)

### WED 1/11

No digging - SC v' wet! - also raining in crypt! - total water penetration of the brickwork, dealt with a few coffins & did some filming with CA but v' slow work rate. - Tony has put MON - WED down as 'no excavation' due to weather - I agree - virtually impossible inside or out to deal with burials properly.

### THURS 2/11

No digging in churchyard, crypt - asked merge to clear coffins for us - not much to do but setting systems etc now seem to be going in & it looks like we will be able to proceed fairly swiftly.

### FRI 3/11

Crypt - quite a lot of coffins encased in Bay 3 & in Bay 2 - plenty of work - also clearing 'sides' in Bay 4 but no coffins to deal with - by end of day - up to date!

SC - started digging & cleared a small amount.

Am - Janek's milled visit with Catherine Karsenak & a friend from MOLTS. all dr.

12:00 pm - Derek Hand visit - went thru update on 'starchen's' remained to date by Nerve.

Up to date in crypt & no more digging in SE. so let stuff go at 2:30 pm.

### FIGURES FOR WEEK:-

Burials = 28      Named = 19      DNA = 13

Base records = 12 (All named)

### WEEK 18 (Wk/W 10/11)

STAFF: DAVID SCOTT      DAVID HALL (4 DAYS)      DAN SYKES

DAN MCCONNELL (4 DAYS)

JULIE ROBERTS (WED - FRI)

WEL RICHMOND (OFF ALL WEEK)

MON 6/11 (mail off all week) (Jill off today)

v' vet.

No digging in SC due to weather.

Tony closed site down at 12:00 noon due to bad weather.

(Dan Sykes/Dan McConnell arrived hotel 9pm due to poor train service etc.)

TUES 7/11 (Julie still off - her flight cancelled)

Due to wet ground & no new work in crypt - got to site at 9:00am (instead of 8:00am) - but Nerve had started in SC

anyway to stopped when uncovered lead coffin. ∴ Dan Mc & David Hall straight to work to deal w Dan Sykes in crypt (could be 1-2 coffins he can get on with).

By end of day - crypt - 10 coffins dealt with, & in Bay 3 they can now move frame forward (will take a couple of days) - we now concentrating in Bay 2.

SC going well - definitely seem to be a much lower density of burials - poss due to 'stickiness' but a bit early to tell for sure.

WED 8/11

AM - monthly PROJECT MEETING. → (C & film crew filmed 1st part i.e. Peter Mitchells Report).

Usual stuff - I have established that SC will be done ~~before~~ before XMAS & gave anyone opportunity to ask for an earlier completion time if possible - although we need to complete as soon as possible to allow max time for earth retention & digging if SC is not complete it will basically be ok until XMAS. (earth retention/dig needs 4 weeks) SO - There's had their chance - no pressure allowed!!

SC continued excavation

crypt - continued in Bay 2 but a bit slow - waiting on 'verap' to uncover more coffins.

THUR 9/11

(DAVID MALL / DAN MCCONNELL BOTH SICK)

Dan Sykes covering SC - proceeding well (lead coffin buried directly in graveyard being reinterred).

(In crypt 4 coffins ready in Bay 2 but 'verap' digging west end of Bay 4 (no coffins!)) So Dan S. will deal with them tom morn.)

FRJ 10/11

crypt - 4 coffins dealt with but then nothing else to do  
SC - continued.

12:30 Tony Mott stopped work so we knocked off early.

Am - site meeting with Janet Miller. (Anna Richie also present) - all happy

WEEK 19 (WK 17/11)

Staff: DAVID SCORE, DAW SYKES, DARKO MARICEVIC  
JULIE ROBERTS, MEL RICHMOND

Sick Thurs/Fri

MON 13/11

Nothing to do in crypt but Bay 3 pos. coffin uncovered by tom?  
SC continued - numerous lead coffin burials - stopped. Spoil remained  
from crypt while we work in adjacent area (no job as they can  
stock pile in Bay 1)  
Darko m. given "Safety induction" by me. Jon returned to site office.

TUES 14/11

crypt - dealt with lots of coffins in Bay 3, mel R. helping  
Ddn S. with recording.

SC - Dealt with lots of burials

→ work proceeding well on both crypt & SC fronts

Garry Ashton - visit to site - happy with progress - went down in  
crypt - all ok. (mentioned 'deep hole' water to Tony - I will  
reaffirm Safety procedures with staff, if we must machine out  
barrow next to section).

WED 15/11

crypt - completed dealing with exposed burials in Bay 3 - now  
waiting on demolition of vault 20

SC - continued - fairly dense burials -

[DS - visit to Spitalfields with Natalie Levanagh (GM) PM.  
- Chris Thomas MOLAS - showed us around (Brian? Connally? osteo?)

THURS 16/11

Dan Sykes sick

Tony McHale asked for figures for Peter Mitchell :-

As of LAST FRI → TOTAL BURIALS = 696

Then add → 200 for SC } estimate  
175 for crypt.

= 1071 TOTAL FOR JOB?

→ Depends on crypt Bay 4 situation - 1 lane mined 2 lanes  
of crypts but it is possible there could be more or perhaps  
more likely less?

BURIALS RELEASED TO NECROPOLIS (listed by them) :-

454	460	255	488
503	459	504	455
500	447	600	777
445	869	813	779
498	621	513	764
461	501	869	601
473	497	542	771
502	655	617	837
196	861	696	
225	506	540	
532	622	457	

41 BURIALS

crypt - 3 same incl - dealt with vault 20 - 2 burials (filmed by CT).

SC - Darko - removed 10 burials - v dense in centre of SC - also  
ephemeral wall structures - pre church? noted on plan - can't make much sense  
of them though.

FRI 17/11

Dan Sykes sick (let him go home am)

Crypt - necessary unearthing more coffins - will need to remove a couple extra to complete H/S frame in Bay 4.

- nothing for us to do today - but should be plenty uncovered by noon.

SC - continued . . . pm - They are shifting spoil round to north side.

Am - Janet Miller visit - all ok

LEAD MONITORING

Blood tests for all staff (Julie spent 2 hrs adding Dr Cobb) will take 1-2 weeks for results - high levels not anticipated but we will see what results show.

Also Dr A.J. Morris HSE Inspector (0171 5562100) on site - not sure what their involvement means but he will clearly be assessing the results of the tests. I was quite straight about our procedures - if we need to tighten up I will be happy to do so.

WEEK 20 (Wk/E 24/11)

STAFF: DAVID SCARF

DARCO MARICENIC

DAN SYKES, (WED → FRI)

MR RICHMOND

JULIE ROBERTS (Sick - THURS)

MON 20/11

(Dan Sykes Sick)

Crypt - no coffins to deal with.

SC continued.

TUES 21/11

(Dan Sykes still sick)

SC continued. - Darts up to speed & doing a good job

crypt D. Sme/mel - dealt with coffins in Bay 4 which need to be removed so Saffery frame 'extensions' can be put in. Also - dealt with some coffins at end of Bay 3.

WED 22/11

Dan S in work - crypt - D. Sme/mel cleared remaining coffins from Bay 3 - now fully clear.

SC continued.

THURS 23/11

(Julie Roberts - sick.)

crypt - Bay 4 - Saffery frame in place & "extension" over current working area - circa 6 coffins exposed - Dan S. / mel dealing - looks like a similar situation to west end containing i.e. a single layer of coffins over a 0.5-0.7 m dump of spoil

SC - spoil management / rain 1st thing. (also hold up for ballast delivery into crypt.)

Serials handed over to Metropolis (listed by them):

440	419	433	417	425	441
462	509	435	429	379	369
507	972	444	430	416	982
322	434	508	456	394	403
402	388	393	439	341	1022

30 ~~BURIALS~~

FRI 24/11

crypt - couple more dealt with in Bay 2. - only a small amount left to clear at east end of Bay 2 now - pushed workers to get this done next week. (concretising pm)

SC no digging - spent management etc.

pm nothing for us to do so left shift go at 12.00 noon.

Figures for week:-

Burials 62.

named 14.

DNA 11.

Gene records 19.

VALUATION: 196 BURIALS.

Janet Miller, Kathleen Kavanagh & Nick Trickett? - EH  
visit to site pm.

WEEK 21 WK/E 1/12/00

STAFF DAVID SCOTTS

DAN SYKES

DARKO MARICOVIC

JULIE ROBERTS.

MEL RICHMOND.

MON 27/11

(mel arrived 12.00 noon)

SC continued

crypt - nothing to do yet but Francis spoke to me & Roylander (presumably) about underpinning of East wall of church from inside crypt (Bay 4)

I said - definitely not until all excavation complete - he wanted to start at east end of Bay 4 as well but I said not without safety protection & on current performance we would be finished before that got erected. no go - underpinners will have to wait - there is no effective way of shortening the timescale although Bay 4 has fewer burials than expected & we may be finished by Xmas but no promises.

TUES 28/11

crypt - dealt with a number of affairs in Bay 4 - Bay 2 being completed. then hopefully the end can be cleared.

SC continued (quite slow as a lot of 'spoil management' required to 'tidy up').

[Cleared 'body bags' from stairs in south lobby of church to cabin - we are doing low resolution only at moment to get some volume shifted]

WED 29/11

crypt - nothing to do.

SC - most of day spent spoil moving to create viable working area at west end of excavations - will save time in long run.

Ang Boyle - visit to site. we are aiming to finish fieldwork by XMAS but we will have cabin till 2nd week in FEB - AB will org osteologists etc to continue on site.

Also - H&S executive inspectors on site - had quite a long chat about archaeology / smallpox etc (-seems vaccination are no longer effective anyway so important thing is to have proper procedures in place in case of exposure). Sounds like they are going to formulate some guidelines for doing jobs like this.

THURS 30/11

crypt - 'vat cart' in Bay 4 - (a coffin with outer wood in good condition recorded). - now  $\frac{1}{2}$  way along this bay.

SC, continued, areas at edge of site - had to mainly "machine out" burials due to high section at south edge of site & unstable backfill of previous strip - bit messy as burials close together but no real alternative.

Dr Cobb sang re lead tests - basically everyone ok. (a few high levels but nothing serious) - he will send this the results in the post.

FRI 1/12

v' wet, - SC digging against church wall but too wet to dangerous to do work in the main area.

cage - removed since further burials from Box 2.

Burials handed over to Verapoli's:-  
(listed by them)

372	403	422	368

## WEEK 22 WK/E 8/12

STAFF: DAVID SCORR, DAN SYVES

DARVO MARJUVIC ANGOZA BOYLE (mon/Tue) ANNSOFIE WITKIN  
MAL RICHMOND - JON GILL (David Stevens) - TUES

MON 4/12 (melt - 11.30 am on site)

crypt - cont. Bay 2 & Bay 4  
SE cont. (burials not as dense?) - opened vault in SW  
corner ready to deal with

TUES 5/12

Jon Gill & David Stevens (Downland Partnership) on site  
to complete crypt building record & photography

crypt - cont. - building's record done - photo won't need to visit  
again.

SE cont. - started digging vault in SW corner & main  
area cont.

Derek Hand visit to site to get more info on structures etc.

WED 6/12

crypt - cont. - Bay 2 now completely clear. - proceeding at  
fast pace in Bay 4. But we will require safety frame to  
be erected before we proceed to the end.

Apparently the underpinners will remove the wall of the end vault  
- I have told Tony this is ok but they must not dig into the soil or

Sample over exposed coffins.

S.C. - cont.

THURS 7/12

S.C. cont.

Crypt cont in Bay 4. - more coffins uncovered in Bay 2 -  
never had not dug out all the soil before concreting! - had  
to break out some of their slab & removed a number of coffins  
- I have reiterated to them that it is their responsibility to uncover  
& clear all remains & I understood the project required them  
to dig to brickwork before concreting. i.e. dig out all soft  
spots.

FRI. 8/12

S.C. continued.

Crypt. All done except vault 8 in NE corner of Bay 4  
- underpinners to knock down wall then monitor we will  
deal.

Figures for week :-
